Becán, examined February 20 to March 4 (N18 degrees, 30.6'; W89 degrees, 28.4') is unique among Maya cities in that the ruins are surrounded by a moat excavated in the natural limestone to an average width of over 50 feet [15.2 m] and a depth varying with the terrain of from 6 to 12 feet [1.8–3.7 m]. It is crossed by seven causeways, some of masonry, some left in the ledge-rock. Water is brought to the moat from a now silted-up aguada on the north side of the city. Architecturally Becán is of the Río Bec type. It has four stelae, two sculptured and two plain. No dates were recovered.

Channa, near Becán, is a small site with one standing building whose north façade has two masonry columns.

The expedition next visited Río Bec. This important city, discovered by Comte Peréigny in 1905–06, was more carefully studied and mapped than was possible in 1933 [Chapter 15.1].

Balakbal, a small new site (N17 degrees, 52.7'; W89 degrees, 35.2'), discovered April 7, shows an arrangement of mounds and buildings like that of Group E at Uaxactún. There is also a ballcourt with long axis east and west. Of five stelae, four are sculptured. From an epigraphic point of view by far the most important discovery of the expedition was the finding of a contemporaneous Cycle 8 monuments at this site, which is the State of Campeche, Mexico, about 5 miles [8.1 km] north of the Guatemala frontier and 32 miles [51.5 km] north of Uaxactún. It bears the dedicatory date 8.18.10.0.0 of the Maya era and is the fifth earliest dated monument yet reported from the Maya area and the earliest known example of a ten-year period marker. The large significance of this discovery lies in the fact that it pushes the area of very early dated monuments some 30 miles [48.3 km] to the north, and corroborates previous conclusions that the Uaxactún region as the earliest center of stone sculpture in the Maya area.

Pared de los Reyes (N17 degrees, 58.8'; W89 degrees, 48.2') is a small group discovered by Mr. Lundell in 1930. It has no stelae and interest centers about the remains of a roof-comb.

La Muralla (N17 degrees, 44.1'; W89 degrees, 47.8'), lying over the border in Guatemala, was studied in 1927 by Mr. Monroe Amsden, who reached in from the Institution camp at Uaxactún. The site contains many mounds, one bearing a roof-comb over 50 feet [15.2 m] long and 15 feet [4.6 m] high, elaborately decorated with stucco sculpture. This type of ornamentation was great favored by Old Empire architects: in its excavations, Maya art apparently reached its highest expression. But due to its perishable nature very few examples have been preserved. For this reason unusual importance attached to the La Muralla figures and Mr. Ruppert accordingly devoted particular attention to making photographic records of such parts of them as remain.

San Francisco (N18 degrees 08'.3; W90 degrees 05'.0), examined April 16 to 18, has many mounds, but no standing stelae or buildings.

Uxul (N17 degrees, 51.7'; W89 degrees 59.3') was the last city reached by the 1934 expedition. It is a long, rambling assemblage of mounds, apparently not carefully laid out. One group is again similar in plan to Group E, Uaxactún. There is a ball-court with long axis north and south. Fourteen stelae, of which 13 are sculptured, yielded 10 Initial Series ranging from 9.9.9.9.18 to 9.12.0.0.0.

15.3.

KARL RUPPERT

Campeche Expedition

YB 37:154–156, 1938

In continuance of the exploration of southeastern Campeche and southwestern Quintana Roo, March, and April of the past season. This was made possible, in part, by generous financial aid provided by Mr. John H. Denison, Jr., who served as epigrapher on the expedition.

Mr. Denison and Mr. William E. Shepherd, the latter as cartographer, landed at Progreso, Yucatán, January 6, whence they proceeded to Mérida. Here they were joined by Mr. Ruppert on January 8. Mr. J. C. Brydon of Mérida kindly loaned the use of a storehouse for assembling and packing equipment and supplies. On February 1 the expedition left Mérida by train for Hecelchekan, Campeche. The following day the journey was continued to the chicle camp of Nohsayah (N18 degrees 44.4'; W89 degrees 14.6'). This portion of the trip, made by airplane in an hour, would by pack mule have taken 10 days. February 4 the party set out with pack mules for the laguna of Central Sabana, where camp was established from February 5 to February 8. From here trips were made to a number of small groups of ruins lying within a distance of from four to five hours' ride.

The first, Payan, to the east of the laguna, is a scattered group of mounds. The highest, which was probably the principal structure of the group, now shows only a few great stone blocks which served as facing. At some distance to the southwest are remains of a building which shows 14 chambers. The west façade is pierced by three doorways and was decorated with stucco masks.

Desprecio, two hours' ride southeast from camp, is distinctive only in a U-shaped structure somewhat reminiscent of similarly shaped mounds seen at Río Bec in 1933.

Buenos Aires, lying four hours' ride northeast of camp, was a group of low mounds and a partially standing six chambered building. The structure carries a roof-comb of the single-wall type. Xaxbil, near the aguada of Garafon, is a small building with two rooms, and has façade decoration of large geometric scrolls and engaged columns at the corners.

On February 11 the expedition moved to Lagunitza (N18 degrees 27.61'; W89 degrees 18.9') where camp was maintained until February 18. The site of Okolhuitz, to the east of the aguada, is fairly large and arranged in two definite groups, each on the crest of a low ridge. Architecturally it is of Río Bec type.

A day's trip was made to the site of Pasión del Cristo, where there are a great many large mounds and three fallen and one standing stela. No dates were obtained by Mr. Denison.

Three days were necessary to make the trip from Lagunita and examine the site of Corriental. In this group is one standing building with two towers. A passageway from a chamber behind one tower extends downward into the fill of the pyramid, through it to the other side, and then upward opening into a chamber behind the second tower.

From February 19 to February 25 the expedition camped at the aguada of Xpuhil (N18 degrees 30.6'; W89 degrees 24.5'). The ruins, lying 20 minutes' walk southwest of the aguada, consist of a few low mounds, except for one remarkable structure defining the west side of a large plaza. This building has 12 rooms and three towers, one placed at either end, and one in the back center. The latter rises 20 m above the podium on which the building rests. The towers have rounded corners and carry false stairways which were ornamented with great stucco masks.

On February 26 camp was moved to Aguada Carolina, and the following three days were spent in studying the ruins of Culucbalom, half an hour's ride to the east. The best-preserved structure defines the north side of a small court. The building contains six chambers and carries a roof-comb of the single-wall type. Of special interest is the south façade, ornamented with four engaged columns each decorated with two seated human figures in low-relief stucco.

While camped at Laguna Carolina Mr. Shepherd made observations for latitude and longitude, which are N18 degrees 34.1' and W89 degrees 27.7', respectively. The aguada at water level had a length of 2/5 mile [0.6 km] and a width of 1/6 mile [0.26 km]. On March 3, Mr. Denison made a trip to inspect some large mounds to the south. They proved to be Becán, the site surrounded by a moat, which was discovered by Carnegie Institution in 1934.

On March 7 the expedition left Aguada Carolina for Santa Rosario by way of So Aguada, Guyitara, Carmalita, and Holaltún. A large group of mounds at Carmalita indicates a once well-planned, carefully laid out city. To the northwest of Holaltún recent milpa clearings have exposed a number of structures. The lure of treasure has led chicleros to dig in some of the chambers' with consequent destruction of material.

The aguada of Santa Rosario was reached March 14 and there camp was maintained until the morning of March 22. The ruins known as Pechal lie half an hour's walk to the south of the aguada (N18 degrees 52.0'; W89 degrees 29.8'). The city was the largest encountered. Several of the buildings, each resting on a podium, show elaborate stucco-decorated façades. The

east court proved of outstanding interest, as it was probably an amphitheater. The court measures 68 m by 75 m and is surrounded on all sides by a continuous mound, broken only in four places, as if for entrances. An examination of the enclosing-wall showed it to be lined on the inner side by a series of 18 to 20 steps. The seating capacity, very conservatively estimated, is placed at 8,000. Four stelae discovered at Pechal were sculptured with human figures, but carried no dates.

The last site visited was that of Peor es Nada (N18 degrees 50.5'; W89 degrees 22.2') where the party stayed from March 22 to March 31. It is a rather extensive site with a number of buildings standing in part, which show ground plans of from six to 14 rooms. Towers, as at Río Bec, were seen on two structures, and there is a roof-comb of the single-wall type, 18 m long, 5.4 m high, and 1.9 m wide. Peor es Nada is the only site where a ballcourt was found. From here the expedition returned to Noh-Sayab and then by airplane, on April 6, to Mérida.

15.4.

E. WYLLYS ANDREWS

Exploration in Southwestern Campeche, Tabasco, and the Department of Petén

YB 39:267–269, 1940

In the course of decades of exploration and excavation, a large part of the Maya area has become intimately known to the archaeologist. Up to the present decade, however, work has been concentrated at the northern tip of the Yucatán peninsula (the "New Empire" area) and at the opposite end in northern Honduras and the lowlands of Guatemala (the "Old Empire" area). In the course of these investigations the intervening country was almost completely ignored, but recently the work of Messrs. Pollock and Ruppert has gone far to bridge the archaeological gap between these two regions. Dr. Pollock has conducted an architectural reconnaissance of the Puuc and Chenes areas in the north. Mr. Ruppert on his several Campeche expeditions has explored the western part of southern Quintana Roo and, the eastern part of southern Campeche. A large gap still remained, including that part

of Campeche south of Champotón and west of La Tuxpena, the part of Tabasco north of the Usumacinta River, and the northwestern corner of the department of Petén in Guatemala.

During the past winter, Mr. Andrews spent several months in a preliminary exploration of this territory. He was accompanied by Mr. Melvin A. Traylor, of Chicago, who, establishing himself at several base camps during the period, made an extensive collection of birds for the Field Museum of Natural History.

The party left Mérida in the middle of December, proceeding directly to Matamoros, Campeche, where by the courtesy of Mr. Cecil H. Branson, of the Laguna Corporation, Mr. Andrews was able to make a trip northward to a group of reported near the chicle camp of Carrizal, then in a large circle to Mocú, Cilvituk, Konhuas, and Esperanza, whence he was able to fly by chicle plane back to Matamoros. Except at Carrizal and Cilvituk, no standing remains were encountered. However, the entire area was covered with concentrated groups of mounds in complete ruin, many of them (such as those at Mocú) of considerable size and extent. An extremely dense population in ancient times was clearly indicated. At Carrizal, the only fragment of standing architecture contained a vault very reminiscent of Tzibanche in its extreme narrowness and "cupola" shape.

Interesting remains were noted on an island in the center of the Laguna Cilvituk, previously visited by Maler in 1895. Two sites were named Isla Cilvituk A and B, to distinguish them from the large remains on the mainland near the village of Cilvituk. In one of these groups was a low substructure with a square temple with flat beam and mortar roof.

From Matamoros, an excursion was made to the village of Pustunich, 100 km south of Campeche near the line of the Ferrocarril del Sureste. Here two sculptured monuments were found which almost perfectly duplicate the style of the sculptural material found in 1937 at Telantunich in Quintana Roo. The resemblance was so startling that these sculptures may safely be classed as organically related members of the complex defined Mr. Andrews' paper on that area. One these, a grotesquely phallic male statue, been re-erected in a shrine for local worship. Under the name of Santo Pus, he is now center of the village's Catholic ceremonial

Returning to Matamoros, the party then flew to Pacaitún on the Río Candelaria for a reconnaissance of this drainage system. Excursions were made to the mouth of the river, and then upstream to the heads of its two main tributaries, the Río San Pedro and the Arroyo Caribe. From Laguneta at head of the Caribe, a trip was made to the chicle center of Aguada Seca to the east. In this entire area no standing ruins were

countered, but the examination was sufficiently exhaustive to permit the conclusion that probably no large remains of this sort will be found here in the future. As in the Matamoros region, however, wherever the terrain was habitable, large and small mound aggregations were found in surprising density, again indicating an unusually dense population in ancient times. Pottery was to be found almost everywhere on the ground, and notes were kept of specific deposits and stratifications to aid in future ceramic study this region.

Finally, Mr. Andrews made a trip to the south, crossing from the Río Candelaria the Río San Pedro Martir, and on to Tenosique on the Usumacinta. In the course of a brief visit to Piedras Negras and Yaxchilán, a previously unphotographed fragment of Stela 38 at the former site was encountered. This fragment bears the terminal date of the monument, 9.12.6.5.9, 9 Ahau 18 Zotz. Connected to this by a secondary series is the further date 5.12.6.5.9, 4 Muluc 7 Zac. The assembly of the fragments of this monument in *The Inscriptions of Petén* apparently includes an eroded fragment which was not part of the stela.

Information was obtained at Balancan regarding a large site one day's journey up the Río San Pedro Martir, and a visit was made possible through the kindness of Don Pablo Ocampo, on whose lands it was located. Maler had heard of this ruin in 1907, and named it La Reforma III, although he did not visit it. As the settlement of Moral is considerably nearer the ruins than the finca of La Reforma, and as Reforma is a confusingly common name throughout this general region, the former name has been given to the ruins. Moral was a very large city, extending in compact plaza groups over several square kilometers. Although many of the mounds are extremely high, no standing remnants of architecture were found. This was partly due to the ravages of time and weather and partly to the fact that many of the larger pyramids had been completely stripped in recent times to fill gullies on the road detouring the two leagues of unnavigable water between La Provincia and Palomillo on the nearby San Pedro. In one of the plazas of the city were found a sculptured stela, a plain stela, and a plain round altar. The stela was carved on four sides, the front and back with human figures, the sides with hieroglyphic dates. Above the standing figure on the back of the monument was a well preserved Initial and Supplementary Series, dating it at 9.16.5.0.0, 8 Ahau 8 Zotz. The style of the monument is unmistakably that of the Petén, in contrast with that of the nearer cities of Yaxchilán and Piedras Negras on the Usumacinta and Palenque to the south. This indicates that the Río San Pedro was an artery of cultural traffic in middle Old Empire times.

Mr. Andrews returned by river to Carmen, whence he flew over the lower Chumpam and Candelaria drainages to Pacaitún. He returned to Mérida early in March.

15.5.

GEORGE W. BRAINERD

Campeche

YB 48:232–234, 1949

The purpose of the fieldwork undertaken in Campeche this year was the linking of the ceramic sequences of Yucatán and the Petén region of Guatemala by excavation at a series of intermediate points in the area lying between them. The work was in charge of Dr. George W. Brainerd, who took six months' leave of absence from the University of California at Los Angeles and from the Southwest Museum for this purpose. Mr. Karl Ruppert, who was thoroughly familiar with the southern part of the area to be worked, was the other member of the expedition.

Previous architectural exploration of this intermediate territory between the northern and central Maya ruin areas had been done by Ruppert (Ruppert and Denison 1943) and by Dr. H.E.D. Pollock [Chapter 2.3]. The standing ruins in the Chenes, which is the northern part of this area, are distinctive and are similar in many particulars of style to those of the southern part of the area, which has been called Río Bec after the site of that name. These two architectural styles (or, perhaps better, this joint style) are in turn easily distinguishable from that to the north in the adjoining Puuc area of Yucatán, and from that of the central or Petén Maya area which adjoins the Río Bec area to the south. The explored Chenes and Río Bec sites are separated by about 100 km of unexplored area which presumably also contains ruins of Chenes-Río Bec architectural style.

Three sites were tested ceramically this season: Santa Rosa Xtampak and Dzibilnocac in the Chenes region, Xpuhil in the Río Bec area. Collections were also made at other sites within 30 km of Xpuhil. Approximately three months were spent in excavation. The next three months were spent in Mérida in recording the collections, to be followed by a month at Los Angeles in analysis and preparation of a report. During the time in Mérida Mr. R. E. Smith gave two weeks to the identification of Petén influence and trade in the

collections. This procedure was of great benefit in establishing approximate chronological equivalence between the Campeche ceramics and the sequence at Uaxactún in the Petén, where stratigraphic phases have been fixed in time by Maya dates on accompanying monuments.

The determination of the correct time relations between the ruins of the Petén and Yucatán areas is of importance both in telling of Maya history and in the dating of the Maya culture in terms of the Christian calendar. The Chenes-Río Bec area, intermediate between the two, is the likeliest place to look for datable connections between them. Its study is also important in the determination of the nature and direction of cultural influence at all periods between Yucatán and Petén.

All three sites dug showed evidence of occupation ranging from pre-stela (Formative) times until somewhat before the period of Toltec influence at Chichén Itzá. In each site, however, one period predominated in the pottery, presumably that of the standing architecture of the site. This period in all cases was characterized by a predominance of the Medium Paste Slateware which also predominates in the Puuc ruins and other of the Classic Period in Yucatán. The occurrence of this pottery at Xtampak in quantity in the terrace underlying stelae, two of which bear Maya dates of approximately 9.16.0.0.0, gives a contemporaneous date for this ceramic horizon in the Maya calendar. This dating by sherd material was reinforced by the finding of cache pottery of Classic ware in the stelae platform. The terminal dates of the period are harder to work out, but some information should appear from the detailed analysis not yet begun. At present there is a suggestion that the occupation of the Puuc sites was somewhat later than, though overlapping in time with, that of the Chenes sites. The beginning date of this pottery is also not closely fixed as yet. The absence of all three sites of clearly defined deposits between the Classic and the underlying Formative suggests either a period of abandonment or a longer use of the pottery we call Classic. At various sites in Yucatán a series of ceramic phases between Formative and Classic have been found and designated by the general term Developmental. Yucatán Developmental pottery occurs very sparingly in the Chenes sites tested.

Dating in the Maya calendar of Chenes architecture at Xtampak is given confirmatory evidence by Smith's classification of the Petén trade wares. The majority of polychrome trade ware sherds from each site tested falls into the Uaxactún subphase Tepeu 2, which Smith dates at 9.13.0.0.0–9.19.0.0.0. Thus the dating of the Chenes and Río Bec architectural styles falls well within the Maya Initial Series Period. The coming detailed analysis of these collections should

limit more closely the dating of the Yucatán periods in reference to the period of these sites.

The degree of cultural similarity among the material of the Puuc, Chenes, Río Bec, and Petén areas is useful in evaluating Maya cultural development. Both Chenes and Río Bec pottery of the Classic Period show preponderant percentages of Medium Paste Slateware, the chief Yucatán ware of this period. This ware is distinctive from that of the Petén. The pottery of each of these three Slateware areas, however, is easily distinguishable from that of the others by differences in detail of vessel forms. The finer monochromes of the Río Bec area are very similar to certain wares of their corresponding horizons in the Petén, whereas the Chenes fine monochromes resemble those of the Puuc area. These degrees of relationship seem at least roughly to parallel the architectural relationships which have been observed.

An additional finding of interest is that of a new Formative phase which seems to precede the Late Formative apparent in nearly all Yucatán sites thus far sampled. The Yucatán Late Formative, as well as that found in the Campeche sites this year, bears certain marked similarities to types of pottery found in the Chicanel Phase at Uaxactún, according to the find-

ings of R. E. Smith. There are also sporadic resemblances to the earlier Mamom Uaxactún Phase. At Dzibilnocac and Xtampak were found deposits of a phase seemingly earlier than Late Formative and showing ware and form resemblances to the early deposit found at Maní under a Late Formative deposit [Chapter 1.31] (YB 41). At Dzibilnocac the deposit of this new phase includes some Late Formative pottery; at Xtampak the diagnostic Late Formative wares are absent. This period may be provisionally called Middle Formative; the Maní deposits, Early Formative. The Middle Formative phase shows less similarity to Chicanel than does the Late, but no similarity to Mamom. The Early Formative seems to show no resemblances to any pottery of other areas thus far known.

The dating of the Early and Middle Formative periods of the northern Maya area is not at present a profitable subject even for conjecture. The Middle Formative collections are small; the Early Formative, although larger, are limited almost exclusively to water jars. The distinctive character of these periods is striking, but further excavation is imperative before they can be properly placed. The study of the cultures sampled this season has scarcely been initiated.

16.0. CALAKMUL

Calakmul is one of the largest and most important of known lowland Maya sites. It is located in southeastern Campeche, north of El Mirador, and some 35 km from the Guatemalan border. Calakmul was first reported by Cyrus Lundell in 1931. The first CIW expedition to the site was in April, 1932, followed by three additional surveys, the last in 1938. In 1982 it was the focus of a project sponsored by the Universidad Autónoma de Campeche, which has produced a new settlement map, the discovery of more monuments, and a series of new excavations. The site core comprises approximately 2 sq km and contains approximately 1,000 structures and at least 117 stelae. Although construction of both of the main pyramidal buildings, Structure 1 and the 45 m high Structure 2, was begun in the Middle Preclassic period, Calakmul was not identifiable as the seat of an important royal dynasty until about 500 AD. It first became a regional power, capable of competing with Tikal under Tuun K'ab Hix (ca. 520–550 AD). The political influence of the site reached its political apogee under Yuknoom the Great. His son, Yuknoom Yich'aak K'ak' (686–695 AD) was vanquished in 695 AD while battling Tikal. The sensational

tomb chamber of this ruler was found in Structure 2 in 1997. The glyphic record of the site ends in 909 AD.

16.1.

ALFRED V. KIDDER

The Calakmul Expedition

YB 31:95–96, 1932

Work at Chichén Itzá was interrupted, in mid-season, by word of the discovery of a large, hitherto unreported Maya city in the archaeological unknown forest region of south central Campeche. Mr. C. A. Lundell, then in the employ of the Chiclé Development Company,

learning of the site from chicleros, explored and named it in December 1931, and later reported it to Dr. Morley, coming to Chichén Itzá in March, where he most generously turned over to the Institution his map and notes.

So important did the ruin seem, from Mr. Lundell's description, and so many inscribed monuments did it evidently contain, that it was decided to equip an expedition for its immediate investigation in order to take advantage of transportation facilities at the same time available through operations of chicle workers in the region, but which might, in another year, not be available. Dr. Morley headed the party and handled the epigraphy; Mr. Ruppert accompanied it to report upon architecture; Mr. Bolles to survey the city; Mr. Strömsvik to turn fallen monuments and to study such artifacts and pottery as might come to light.

Four weeks were devoted to the trip, two weeks being spent at Calakmul. The five days' journey in from the city of Campeche by boat, mule-drawn trolley, auto truck and mule-back was arduous in the extreme. It was made possible by the most helpful cooperation of Mr. Brydon of the Chicle Development Company and the invaluable assistance of Sr. Francisco Buenfils

of Mérida, a large chicle operator. The ruins proved to be those of a very extensive Old Empire city. It is remarkable for the unprecedentedly large number of its monuments. No less than 103 stelae were found, of which 75 percent are sculptured, and of which the dates of nearly 50 were deciphered by Dr. Morley, covering the period in Maya chronology from 9.9.10.0.0 to 9.19.0.0.0 (364 to 550 A.D., according to the Morley-Spinden correlation). The height of ancient activity at Calakmul would thus appear to have taken place during the middle to late part of the Old Empire period. The nature of the sculpture indicates that the city was a thriving provincial center, evidently colonized from Petén. Its situation in a region between the previously known sites of Petén and those of later times in northern Yucatán gives it great archaeological importance. Word of other large ruins in the vicinity, one of which was visited by Messrs. Ruppert and Bolles, and found to contain sculptured monuments extending into the Cycle 10, offers ground for belief that much significant information upon Maya history awaits recovery in this region. It is planned to continue exploration there in 1933.

17.0. EDZNÁ

In 1928 the Mexican archaeologist Federico Mariscal published some drawings and plans of Edzná. Sylvanus G. Morley and Enrique Juan Palacios later deciphered some of the dates on the stelae. The first extensive exploration of the site was undertaken by Alberto Ruz Lhuillier and Raúl Pavón Abreú in 1943. They identified the extent of the site core and the major features of the Temple of Five Stories and Ruz Lhuillier published an account in 1945. Pavón Abreú conducted further work in 1958 and 1962, and the Temple of the Five Stories was partially restored. In 1968 a survey of the site core and some peripheral areas was made by George F. Andrews. In 1970 additional excavation and restoration was undertaken by Pavón Abreú and Román Piña Chan for Instituto Nacional de Antropología e Historia de Mexico, and in 1983 the New World Archaeological Foundation archaeologists including Ray T. Matheny and Donald W. Forsyth reported on the hydraulic systems and ceramics at Edzná. From 1986 through 1989 major excavations and structural restorations were undertaken by Pavón Abreú and Luis Millet Camara of the Campeche Regional Center of Instituto Nacional de Antropología e Historia de Mexico,

and it was reported by Benavides Castillo in 1989 and 1990. Guatemalan refugees formed part of the work force, and funds were provided by agencies of the United Nations and Mexico devoted to helping refugees. In 1991 additional excavation on the north side of the Main Acropolis and consolidation of the Temple of the Five Stories were undertaken.

17.1.

SYLVANUS G. MORLEY
Report on Edzná

YB 26:263–266, 1927

On January 13, 1927, Mr. Nazario Quintana Bello, Inspector of Archaeological Monuments for the State of

Campeche, discovered an important Old Empire city, some 40 miles [64.4 km] southeast of Campeche, the state capital, and 8 miles [12.9 km] east of the modern village of Tixmucuy. A temple, five stories high, was the principal object stressed in the press reports of the discovery and the name of *Tixmucuy* was incorrectly attached to the city.

Early in March, Messrs. Reygadas, Palacios and Mariscal visited this site in behalf of the Direction of Archaeology of the Mexican Government, and made additional discoveries of even greater scientific importance. Several hieroglyphic monuments were found, and Mr. Palacios succeeded in deciphering on the front of Stela 2 an exceedingly difficult and very much weathered text, recording the Initial Series date, 9.15.0.0.0, 4 Ahau 13 Yax (ca. 472 A.D.), which fixes the chronological position of the city.

This new Initial Series makes the fourteenth to have been found in Yucatán,¹ and the third in the State of Campeche, the other two being the one from Holactún on the savanna of Xalumkin south of the railroad station of Dzitbalché [Chapters 1.6 and 1.12] and the other from the Island of Jaina on the northwest coast [Chapter 1.12].

On May 15 and 16, Dr. Morley and Messrs. Ruppert and Crandall visited this site in behalf of the Institution, discovering 15 additional monuments, bringing the total of sculptured stelae to 17, and a hieroglyphic step in front of the principal temple. At this time also, the true name of the site was ascertained from the inhabitants of the nearby village of Tixmucuy.

The local name for this group of ruins is *Etzná*, meaning in Maya *etz*, a grimace, or a face, in the sense of to make a face and *ná* house, perhaps "The House of Grimaces," would be a free translation. The Indians of the region have a tradition that if one is hungry, and leaves money on the stones at Edzná, returning later, a good meal will be found in its place.

Finding the name Edzná so clearly attached to the site, and not that of Tixmucuy, the name of the modern village nearest there to and under which the first press notices thereof had gone forth, Dr. Morley asked permission of the Direction of Archaeology at Mexico City to make this change in nomenclature before such a misleading designation should become fixed. This was graciously granted, and the local name Edzná was accepted for the group.

The ruins of Edzná indicate that it had been a place of considerable size, a large provincial Old Empire city, although not so large as Cobá [Chapter 34.1]. The large Acropolis is an enormous construction measuring more than 500 feet on a side and some 25 to 30 feet in height. From the broad platform thus provided, rise four temples on the four sides of a court, that on the eastern side (that is, facing west) being the Temple

of The Five Stories, noted in the first press dispatches. The four lower stories of this edifice are built against the side of the supporting pyramid, in tiers receding toward the summit, a broad central stairway leading from the court level to the fifth story above.

This had originally been composed of two chambers, one behind the other, but the outer front wall had entirely fallen, leaving only the inner chamber intact. Although the exterior walls had been made of faced stone, the individual blocks were very small and not overly well executed. The arch stones were not shaped as in New Empire times, the slope of the corbel being achieved by a liberal stucco finish, now fallen, leaving the rough butts of its constituent elements exposed. Against the back of the inner chamber a large plain slab of stone had been let into the wall. This had every appearance of being a stela, but was without carving. The wooden lintel over the doorway leading into this chamber was of four sapote beams, all in good condition. This fifth story is surmounted by a roof-comb, in fairly good condition.

Perhaps the most interesting feature connected with the Temple of The Five Stories is the presence of one or more hieroglyphic steps in the stairway leading to the fifth story. Such, however, is its present chaotic condition, the component blocks having fallen and rolled hither and thither, that it was impossible to verify to what extent the risers of the individual steps had been carved. Near the bottom, one step and possibly two, showed hieroglyphs carved upon the riser. Each glyph is presented in a single cartouche with rounded comers. Unfortunately some one had torn a number of blocks from their original positions and thus destroyed the original sequence, a matter of vital importance in deciphering Maya texts. Considerable excavation, particularly at the northern side of the stairway, will be necessary before the beginning of this inscription (that is, the left half of the step, facing it) is disclosed.

The Small Acropolis lying just south of the Large Acropolis, and practically joining it, is even of greater scientific interest, in that here were found all the 17 sculptured stelae thus far reported at Edzná.

The Small Acropolis is surmounted by five temples, the one on the western side irregularly facing west, that is away from the court behind it, upon which the other four face. The western temple, however, would appear to have been the most important, since arranged in tiers in front of it, there are at least three rows and possibly four on the general ground level at the western base of the Small Acropolis, another possibly halfway up the slope, and a last row of two stelae on the terrace above directly in front of the temple, in all 16 of the 17 stelae thus far found at this site. The remaining monument, Stela 17, stands in front of the temple on the eastern side of the plaza above.

Fortunately most of the monuments associated with the Temple of the Sixteen Stelae had fallen with their sculptured faces downward in ancient times, so that the relief in many cases is still beautifully preserved. Of the 16 monuments in front of this temple, only two (Stelae 2 and 11) were found standing, by Mr. Reygadas and his associates in March; and it was on the former that Mr. Palacios succeeded in deciphering the Initial Series date 9.15 0.0.0, 4 Ahau 13 Yax, the only one thus far found at Edzná.

Of the 14 remaining monuments, three (Stelae 5, 13, and 14) had fallen with their sculptured faces upward so that most of their relief had been destroyed. This left 11 monuments (Stelae 1, 3, 4, 6, 7, 8, 9, 10, 12, 15, and 16) which were turned over to show their sculptured faces by the Carnegie Institution Expedition in the forenoon of Sunday, May 15, probably the greatest number of Maya monuments ever exposed at one time to the light of day.

The Edzná monuments, with the single exception of Stela 12, are sculptured on one face only, the back and sides being dressed, but plain; many if not most of the stelae have rounded tops. The commonest subject portrayed is a large principal figure of a ruler or high ranking priestly official standing upon the back or the stomach of a very obviously inferior captive. This subject is portrayed on Stelae 1, 5, 7, and 11, and probably upon Stelae 2, 3, 4, 10, 13, and 14 as well although the effect of erosion in the latter group makes impossible certain identification of the respective "captives."

The two monuments, Stelae 15 and 16, that formerly stood directly in front of this temple, for which reason they are probably of latest date, show a different treatment. The former is divided into two horizontal panels, the upper presenting the principal figure with some sort of a ceremonial baton in his hands and a small seated human figure at his feet; and the lower, two smaller human figures facing each other, with a panel of glyphs between them. Stela 16 is divided into three horizontal panels, each presenting two small human figures facing each other. Above there seems to have been a single row of glyphs. Stela 1 at Jaina, also in the State of Campeche, possibly dating from 9.11.0.0.0, 12 Ahau 8 Ceh, shows a similar division of its front into three horizontal panels, the upper one occupied by four seated human figures facing the center two on each side, the middle by a larger principal figure with smaller ones at its right and left, and the bottom one by a single human figure.

Stylistically considered the two most important monuments at Edzná are Stelae 8 and 9; indeed so unusual is their treatment, the nature of the design and its arrangement that they stand in a class by themselves without close analogues throughout the range of Maya stelae.

The subject portrayed on each monument is a pair of standing human figures back to back, the medial vertical axis of the front of the stelae passing between them. The medial vertical axis of each figure coincides with a front edge of the plinth in such a way that half of each figure appears on the adjoining side. A slight stylistic improvement is noted in Stela 8 as compared with Stela 9. In the latter case, although half of the upper part of each figure appears on the adjoining side, both legs are unnaturally forced on to the front of the plinth, giving a very grotesque twist to each body. In Stela 8 this defect has been remedied by the very naturalistic device of permitting the figure simply to straddle the edge, one half of each body from the elaborate head-dress to the sandal, appearing on the front of the plinth, and the other half in each case on the adjoining side.

The arrangement and length of the inscriptions in Stelae 9 and 8, also show corresponding development. On Stela 9, there is a single band of five glyph blocks across the top of the front; while on Stela 8, the inscription begins with a single glyph-block at the top of the left side, thence passes across the front in four glyph-blocks and finishes at the top of the right side with another single glyph-block.

Concerning the dates of the Edzná stelae, owing to the fortunate decipherment of the Initial Series on Stela 2 by Mr. Palacios of the Direction of Archaeology, at least one date is surely fixed in the history of the city. In addition, Dr. Morley found two other Period Ending dates, on Stelae 5 and 9. The three known dates at Edzná are as follows:

Table 17.1.1. Calendrical Decipherments, Edzná.

Stela 9	9.11.17.0.0	9 Ahau 3 Mol	circa 410 A.D.
Stela 2	9.15.0.0.0	4 Ahau 13 Yax	circa 472 A.D.
Stela 5	9.18.0.0.0	11 Ahau 18 Mac	circa 531 A.D.

These three dates, and especially the second one, which is an Initial Series, fix the chronological position of Edzná as extending at least from the middle of the Middle Period of the Old Empire down to the height of the Great Period; and its geographical position—far north of the center of the Old Empire region (that is, the Department of Petén, Guatemala) as clearly indicates that it was a peripheral and correspondingly provincial city, but at the same time of no mean importance in the world of its day.

NOTES

1. Nine Initial Series were discovered in Yucatán in 1926, one at a small site called Ichpaatún on the shores of Chetumal Bay, Territory of Quintana Roo, by Dr. T. Gann,

and the other eight at Cobá, in eastern Yucatán by the Carnegie Institution of Washington [Chapter 34.1].

2. There is evidence at Piedras Negras, Naranjo and Quiriguá, where the sequence of the hotun markers is especially long and unbroken, that the latest monument

in each plaza, not only occupies the most important position in that particular assemblage of monuments, but is also the most beautiful. Examples of this are Altar 1 at Piedras Negras, Stela 32 at Naranjo, and Zoomorph P at Quiriguá.

18.0. CHIAPAS

18.1.

EDWIN M. SHOOK

Yucatán and Chiapas

YB 54:289–295, 1955

Except for the brief time occupied by field activities at Mayapán, Shook spent the major portion of the past season in Mérida. There, at the Department's ceramic laboratory, he studied the pottery of Mayapán, assisted Berlin with his report on Tabasco, and recorded a number of privately owned archaeological collections. Shook also devoted about five weeks to exploration of ruins in the environs of Mérida, on the coast of Campeche, and in the central highlands of Chiapas.

The private collections in Mérida range in size from several specimens to over a hundred, usually of pottery, recovered from sources widely dispersed throughout the Yucatán peninsula. Though often lacking important information on exact provenience and association, these collections provide complete examples for study of many ceramic types previously known only from sherds. In rare instances, the contents of a single tomb or grave have been retained by the collectors, and in such cases contemporaneity and cultural relations may be established from association of pottery types.

Within the modern city of Mérida and on its outskirts, the last vestiges of the preconquest settlements are fast disappearing. The ancient structures are being demolished to clear space for new factories, houses, streets, and the like, or because the archaeological mounds provide a more readily accessible supply of building stone than do the quarries of native limestone. An effort was made to map, photograph, and collect sherd samples from as many of the archaeological sites as time permitted. The following ruins were, briefly visited and recorded.

Tecoh is situated on the lands of Hacienda Tecoh, 6 km south of the central plaza of Mérida. Twenty or more ancient house mounds and low platforms, several rectangular mounds 2–3 m high, and one pyramidal structure approximately 8 m high are arranged around a cenote with a permanent water source and, a spacious natural cave. The cave, now dry, may once have had a shallow pool of water, but its principal use appears to have been for quarrying *sascab* (lime gravel) for building purposes. The ancient quarrying on the

cave's cast side created a low-ceilinged chamber fully 25 m in diameter. The entrance from the natural cave to the large artificially dug chamber had been closed by a thick stone wall except for a single narrow, low-roofed passage. A search by flashlight of the pitch-dark room resulted in the recovery of only a few potsherds around the floor, edges and near the entrance passage. Outside, on the cave floor and in the fill of a collapsed part of the masonry wall, were potsherds in abundance. An unselected surface collection included a few Preclassic, a preponderance of Early Classic, and several Late Classic and Early Postclassic sherds. Among the latter was a decorated spindle whorl similar to some from deposits of the Toltec Period at Chichén Itzá.

The cenote has a roughly circular orifice and a rocky floor-sloping down to a deep, pool of water about 20 m from the entrance. A well-worn path with a few artificially cut steps leads to the water's edge. Along one side of the path, crudely sculptured in the natural rock, is a grotesque writhing serpent.

The Tecoh mounds, now almost entirely robbed of facing stones, are identified by featureless heaps of small dry rock fill. A careful search among the rock piles disclosed that Late Classic Medium Paste Slateware sherds predominate over other pottery types, though Preclassic and Early Classic types are present. A few scattered cut and dressed wall stones also suggested that the major occupation of the site was during the Late Classic Puuc Period.

Quinta Miraflores is apparently a small site, as remnants of only three mounds remain. The ruins are located in the gardens 100 m east of the main house of the property called Quinta Miraflores, 4 km east of the central plaza of Mérida. The present small acreage of the quinta is surrounded by a residential section which formerly was a part of Quinta Miraflores. Two of the archaeological mounds have been reduced by quarrying to barely discernible outlines, but the third retains some architectural features. The local people report the last to have been approximately 10 m high before quarrying brought it to its present height of 1.5 m. Exposed are vertical and sloping terrace walls, lime-plastered stairways, and floors of four successive building stages. The structure in each stage apparently had been a rectangular platform, with steps on either the east or the west side, supporting a building of perishable material. There was no evidence of vaulted masonry buildings. Substructure walls were built of rough uncut stones, then surfaced with lime plaster. A collection of 900 potsherds was obtained from the fill and general debris of the mound. The majority of the sherds were derived from a midden of charcoal, ash, bone fragments, and so on, outside and at the base of the second-phase platform. This midden appears to have

been normal household rubbish thrown over the edge of the platform.

The entire sherd lot from this Quinta Miraflores mound belongs to the Preclassic Period and conforms particularly well with what has been termed the Late Formative stage. There are no identifiable unslipped wares even among the high percentage of jar sherds, nor are there jar handles. It is significant that jar handles are lacking in all Preclassic material Shook has examined from northern Yucatán. Among the 900 sherds, one from a flat-bottomed, low flaring-walled bowl shows the mark of a foot attachment. It could not be determined whether the secondary support had been a solid nubbin or a hollow foot. The evidence from Quinta Miraflores clearly demonstrates simple but formal architecture with four successive rebuildings of the same unit during a late phase of the Preclassic Period.

Colonia Miraflores is an archaeological site of at least six mounds from 1 to 4 m high, 0.5 km south of Quinta Miraflores on lands formerly belonging to the same property. The area, on the southeast edge of Mérida, 4 km from the central plaza, is now a real estate development called Colonia Miraflores. The ancient structures, just north of the highway to Kanasin, are being demolished for building material. In several there are lime concrete floors exposed at different levels, showing a sequence of building activities. In the mound debris are a few well-cut and dressed wall and molding stones and colonnettes of types commonly associated with Late Classic Puuc-style vaulted buildings. The pottery and stone artifacts from the surfaces and fill of the mounds indicate a long period of occupation, extending from the Preclassic, through the Classic, into the Early and the beginning of the Late Postclassic Period. The majority of the sherds and several restorable vessels are of Medium Paste Slateware, confirming the architectural evidence that the site flourished mainly during Late Classic Puuc times.

Tihoo is the major pre-conquest site over which is built the central part of Mérida. Further information was gathered during the past season from oral and written sources and personal observation regarding the distribution of archaeological mounds around the center of Mérida. Only the larger structures have been recorded in published sources or are remembered by living inhabitants. Of the many units, traces of four exist today. The collection of pottery from the Franciscan monastery mound, made by R. H. Thompson and Shook in 1951 [Chapter 4.17], was re-examined. Among the pre-conquest material, there were no sherds identifiable as Preclassic, and just a few Early Classic ones. The majority are Late Classic Medium Paste Slateware, several are attributable to the period of Toltec influence in Chichén Itzá, and a

fairly sizable lot are Black on Cream, a common ware in the earliest levels of the Mayapán Period. The absence of Mayapán Redware sherds in the Tihoo collection suggests that Black on Cream may have been produced in northern Yucatán before, and continued in vogue for some time after, the development of Mayapán Redware.

Xcanatun is a major archaeological site 16.5 km north of Mérida and 0.5 km west of the highway to Progreso. The location of the ancient settlement had been well chosen for water supply, as four small cenotes exist within the confines of the ruins, each opening to the shallow water table approximately 2 m below ground level. The continued ruthless destruction of this great site for road building fortunately was stopped this year through the energetic protests of Dr. Alberto Ruz L., Government Inspector of Ruins for Yucatán. The foundations of six major structures at Xcanatun are recognizable, as well as numerous lesser mounds and platforms. The local workmen reported that the largest unit, before quarrying began, stood 20 m high and measured 80 m square at the base. The structures are formally arranged around several rectangular plazas, the principal one being elongated with its long axis north-south. Throughout the site and on the periphery are many low terraces or platforms retained by walls of large uncut stones laid without mortar. These terraces presumably supported houses of perishable material. There was no cut building stone or sculpture around these terraces or in the debris of the partly destroyed larger central structures. The latter had terrace and free-standing walls exposed, but no evidence of Maya vaulting. Room walls, though heavy, apparently supported beam and mortar or thatch roofs. Walls were constructed of rough, undressed stones and were smoothly surfaced with lime plaster. Floors of rooms, terraces, and plazas had been finished with a hard white to salmon-color lime concrete. Each major structure showed many-successive rebuildings, suggesting a relatively long period of development.

Pottery collected from the fill and debris of the larger mounds, including a restorable jar containing an infant's skeleton, proved to be entirely Preclassic. A few of the sherds conform to types recovered at Quinta Miraflores, but most of the material suggests a ceramic phase older than Quinta Miraflores. A single low mound, partly cut away, had in its debris weathered fragments of an Early Classic lustrous monochrome jar, and on the surface away from mounds were a few weathered sherds of Late Classic Medium Paste Slateware and Fine Orange. The ceramic and architectural evidence demonstrates that Xcanatun flourished as a major center during the Preclassic Period.

Soblonké, a small site 9.2 km north-northwest of Mérida, on the south-edge of the highway to Sisal,

lies at the southeast edge of the village of Caucel, which is built on and around another archaeological site [Chapter 1.40]. The ruins consist of six low mounds from 0.5 to 1.5 m high and a larger structure 3.25 m high. The last has been sectioned by quarrymen, exposing vertical and sloping substructural walls, built of rough, uncut stones and surfaced with lime plaster. The construction is of the same type as that at Quinta Miraflores and at Xcanatun, and again, only Preclassic pottery comes from the mound fill and debris. The workmen quarrying the mound had encountered, just before Shook's visit a burial of a male adult beneath the lowest floor and just above bedrock. They described the position of the skeleton as extended with head to the east. The several pottery vessels accompanying the body had been smashed by the workmen's picks, but many, of the fragments were recovered. These were flat-bottomed bowls of large diameter with heavy, straight flaring walls and with all-over glossily polished, crazed monochrome slip. The colors range on the same bowl from red to brown to black where fire-clouded. These vessels and sherds conformed to the principal types found in the major structures at Xcanatun. A few sherds of Medium Paste Slateware were encountered on the ground surface at Soblonké.

Tuc is a small site 5 km north of Caucel and approximately 10 km northwest of Mérida. Except for stone-robbing for fencing the henequen fields surrounding the site, the ruins of Tuc have not suffered such extensive damage as the sites previously described. A single pyramid, 12 m high, dominates the site and occupies the west side of a small plaza with lower temple mounds or platforms on each of the other three sides. Low mounds and terraces surround this ceremonial nucleus for several hundred meters. The pyramidal unit retains traces of a stairway on the east side, terraces of rough stone masonry, and the base courses of the temple's back wall. The position of the wall and of uncut stone masonry on the pyramid summit suggests a single-room temple facing east. Elsewhere at Tuc only one cut and dressed building stone was observed; it lay in the debris of the platform closing the north end of the central plaza. No pottery could be found on the surface. The placement of the principal occupation of Tuc in the Classic Period, on the basis of site arrangement and the few architectural details, is little more than a reasoned guess.

Ucu, a site consisting of a single mound 8 m high in 1951 [Chapter 1.41], has only traces of the mound left. All except the southern fringe has been torn down to bedrock. The destruction since 1951 disclosed that the structure contained an important architectural and ceramic sequence beginning with a Preclassic unit with rough uncut stone masonry walls, probably a

rectangular platform. How many rebuildings of the primary unit took place could not be determined, but eventually the whole was buried by an Early Classic pyramidal substructure with a stairway on the south side. This unit also probably underwent successive increments before the final Late Classic Puuc-style structure was erected over the older building. Remnants of the vaulted Puuc-style temple atop the pyramid were observed in 1951. Walls were faced with cut and dressed veneer stones set in excellent lime mortar and surfaced with a thin, hard lime plaster.

The small sherd sample collected in 1951 from the Ucu structure was considerably enlarged during the past season. Though hopelessly mixed from surface to bedrock by the quarrying operations, the material could be segregated typologically by comparison with controlled collections from Yucatán. Preclassic types comparable to wares found in Xcanatun and Soblonké were relatively frequent. Early and Late Classic types were almost equally well represented, the best diagnostics being Lustrous Monochrome jars and Medium Paste Slaware.

The above information, coupled with that gathered in previous field seasons, may be summarized as follows. The small area encompassed by the city of Mérida and its immediate environs contains architectural and ceramic evidence of considerable population, possibly continuous, from Preclassic (Middle Formative?), through Classic, into Postclassic times. The earlier phases of Preclassic, and the final period before the coming of the Spaniards, most of which was the time of political dominance of Mayapán, are lacking in the Mérida area. That no remains of these phases have come to light is probably due to the paucity of search by archaeologists. The brief catch-as-catch-can survey of the past season has broadened our knowledge of the Preclassic Period in northern Yucatán and demonstrated that large and small sites with permanent stone architecture of ceremonial, civic, and probably domestic nature flourished long before the so-called florescence or Classic expression of Maya culture.

A brief exploration by motor launch was undertaken along the west coast of the Yucatán peninsula from Campeche to Sisal. Archaeologically this coastal strip north of the Island of Jaina is known only to professional pot hunters and a few fishermen living in widely separated villages. The following sites were visited.

Jaina, 36 km north of Campeche, had previously been visited by the writer [Chapter 40.4]. This time a more thorough study was made of the limited habitation area on the island. Tightly concentrated around the temple mounds, and interrupting what normally would be an open plaza between major public build-

ings, were low rectangular house platforms. These were faced with vertical walls of cut and dressed block masonry, the same as that used in the pyramid terrace walls. Adjacent to these house platforms, pot hunters' pits disclose up to 2 m depth of household, refuse, heavily sown with human burials. Often a skeleton, either of a child or of an adult male or female, is buried tightly flexed in a large pottery urn. The stratigraphy clearly shows that many of the urn burials were inserted into pits dug through old, horizontally bedded refuse; others were sealed by post-burial deposits. Grave furniture may include small ornaments of jade, artifacts of shell and bone, pottery vessels, and figurines, figurine whistles, flutes, and drums of pottery. The articles, if space permitted, were placed with the body inside the urn; otherwise, offerings were laid around the outside of the containing vessel. The rubbish accumulation, evidently from households, contains ash and charcoal lenses, quantities of broken pottery predominantly of coarse unslipped utilitarian wares, fragments of manos, metates, obsidian flake blades, and chipped chert blades, and animal, bird, and fish bones. The inhabitants of Jaina evidently preferred refuse deposits around the house for interment of their dead, or else no other suitable ground was available. Certainly the tiny island was thickly populated during Late Classic times. No earlier material has so far come to light, and only an occasional surface fragment indicates habitation after the Late Classic Period.

Isla de Piedra, approximately 8 km north of Jaina, is a small island about 200 m in diameter barely detached from the mainland. The land area rises gradually from a mangrove swamp next to the mainland to a 5 m cliff on the ocean side. The small archaeological site, of about a dozen house platforms and low mounds concentrated around courts, is on the west half of the island. Numerous pits have been dug by treasure hunters. Pottery and artifacts, the former severely weathered, occur in abundance in the upper 30 cm of the site and sporadically to 50 cm depth. The eroded condition of the sherds permits only a provisional suggestion that Isla de Piedra may have been a short-lived coastal village at the beginning of the Late Classic Period.

Huaymil, 8 km north of Isla de Piedra and 16 km from Jaina, is a small island clump of mangrove opposite the mouth of the Río Huaymil. The ruins lie on the north bank of the river, 2 km inland from the sea, on the first land sufficiently elevated to permit habitation. Mangrove swamp extends from the archaeological site to the sea. A thorough exploration of Huaymil was not possible in the time available. The ruins are enveloped in part by dense, low jungle growth, in part by tall savanna grass. Shook was able to observe only what he believes to be the western edge of the site.

Here a series of tightly enclosed courts are surrounded by colonnaded buildings, some vaulted, and temple structures on high, steep-sided pyramids. One pyramidal mound 12 m high apparently faced north to a court on the edge of which stands *in situ* the bottom third of a carved stela. The upper two-thirds of the monument is missing but may lie buried in the surrounding debris. The stela, of fossiliferous limestone, is plain on the back and the two narrow edges, but the front bears a framed panel containing a standing human figure with feet pointing outward. One partly exposed colonnaded building has a triple entrance formed by two columns, each a single stone reaching to lintel height. The doorjambs and lintels also are single, full-width stones, and the walls are faced with moderately well cut and dressed stone. The structure has two long parallel vaulted galleries with four or more columns acting as medial supports.

The pottery collected from the back-dirt of pot hunters' excavations and from the general surface of the site is predominantly Early Postclassic. Well represented are typical wares and forms commonly found in Chichén Itzá during the period of Toltec influence. These are X Fine Orange and Chichén Medium Paste Slateware jars and bolster-rim basins. The sherd sample contained no Tohil Plumbate, but in a private collection in Mérida, reported to be from Huaymil, there are a number of whole Tohil Plumbate and X Fine Orange vessels.

Huaymil may have been an important Maya center with stelae and Puuc-style architecture at one time, and later, during the Early Postclassic, have come under the same Toltec influence that dominated Chichén Itzá.

North from Huaymil along the coast past Isla Arena, no archaeological site with mounds was known to the local fishermen questioned. They all mentioned Punta Canbalam, about 6 km north of Isla Arena as a place where pottery was abundant. This information proved to be correct.

Canbalam is a long, narrow beach of unconsolidated seashells that is separated from the mainland by an estuary and mangrove swamp. The maximum elevation is 1 m above sea level, and the beach is frequently submerged during storms. Strewn for at least 1 km north-south along the white beach and embedded among the shells to sea level are quantities of water worn potsherds and stone artifacts. The amount of pottery precludes any possibility that Canbalam was a seasonal camp site, and against such a supposition, too, is the lack of fresh water and the precariousness of existence on a low beach exposed to storms. An alternative theory to explain the heavy deposit at Canbalam is that the point once was much more extensive and higher, like Isla Arena, Isla de Piedra, and Jaina, and

had an adequate source of fresh water, and that a sizable ancient settlement occupied this point of land. Centuries of wave action may slowly have cut away the land area and left today just a narrow low strip on the inland side with a fringe of refuse deposits from the old habitation area. The recognizable sherds in the collection from the beach were Late Classic types, including Fine Orange.

The sandbar beginning south of Celestún and paralleling the mainland around northern Yucatán reportedly has shell mounds, but Shook saw none from Celestún to Sisal.

Late in the field season the opportunity was taken to join, in an advisory capacity, a survey expedition into the central and eastern highlands of Chiapas, Mexico. The objective of the expedition, sponsored by the New World Archaeological Foundation, was to locate Preclassic sites for future intensive excavation. Considerable information was gained in this archaeologically little-known region, particularly in the drainage of the Río Grijalva. The previously reported ruins on the east bank of the Grijalva at Chiapa de Corzo were found to be a major site, many of whose large structures were erected during the Preclassic Period. Upstream about 40 km from Chiapa de Corzo a concentration of archaeological remains was encountered along both sides of the Río Grijalva, centered around the modern town of Acalá. Most abundant were Preclassic and Late Classic sites, though it is likely that further investigation will disclose Early Classic and Postclassic remains.

The Acalá region is characterized by rolling to mountainous topography sectioned by the Río Grijalva. On each side of the river there are a number of small, level, exceedingly fertile terraces which have been built up of river-deposited silts from repeated flooding. The level of these terraces is about 12 m above the April 1955 water level. In geologically recent time the flood deposition stopped, and the Grijalva has since cut its present channel, leaving exposed sections of the silt terraces. A study of these river banks revealed cultural material of Preclassic date in the upper 4 m of soil, and Late Classic remains which were limited to the surface level except where deposited in pits intrusively dug through the horizontally stratified silts.

A sherd-bearing, Preclassic midden 30–75 cm thick was discovered deeply buried in the river bank opposite Acalá, just below Puerto Mexico. An exposed cross section of the midden, 18 m wide, showed its east-west limit, but knowledge of how far the deposit extends into the bank must await future excavation. Shook sank a pit 2 m square, using the river bank as one side of the cut, in order to sample the midden, which lay 2.3–2.9 m below the present valley floor. The upper 1.7 m represented successively deposited

layers of fine, sandy loam containing only a few eroded potsherds. This was followed by an occupation level, 1.7–2 m below the surface, composed of charcoal, ashes, sherds, and stone artifacts in a matrix of gray-brown sandy loam. Directly below was another distinct 25 cm thick layer of light yellow-brown loam which effectively sealed over the midden first observed in the river bank. The cultural material from the 25 cm stratum conformed generally with that from the lower deposit and may have been contemporary surface rubbish washed over the midden during the floods which sealed the main deposit. The latter, in an area 2 m square, produced an estimated 8,000 to 10,000 pottery fragments, besides typical midden material of ashes, charcoal, charred seeds, animal and bird bones, burned fragments of adobe bearing pole impressions, some shell, bone, and a quantity of stone artifacts.

This large body of unmixed Preclassic material, probably representing a single phase, provides a datum of reference for future investigations in central Chiapas. The common pottery types were an unslipped coarse brown ware jar without handles and with a straight flaring neck to a direct rim, and an all-over slipped and polished red, red-brown to brown ware

bowl with flat base and straight vertical or flaring wall to an out-curving or everted rim. A few small solid and hollow nubbin feet were found, and several larger hollow feet tapering to a flat bottom. Vessel decoration other than slipping and polishing was rare. Fragments of four hand-modeled figurines of Preclassic type came from the midden. There were no comales, and only two uncertainly identified sherds suggesting incensarios.

Elsewhere in the Acalá region samples of Preclassic pottery were recorded, some stylistically predating and others postdating the Puerto Mexico midden types. Present in these insecurely anchored collections were vessels and sherds of White-Rimmed Black Ware, a pottery found in greater abundance in the Olmec sites of Tres Zapotes and La Venta.

Two Late Classic Period sites, Cupia and Laguna Mora, in central Chiapas, are especially noteworthy because the ceramics of both indicate close trade relations with the Gulf coast plain of Tabasco and the central highlands of Guatemala. Also, sherds of San Juan Plumbate occur at Cupia and Laguna Mora, the farthest northwest this type of Plumbate has yet been reported.

19.0. BONAMPAK

Bonampak is a Classic period site in the state of Chiapas, Mexico, about 30 km south of Yaxchilan. It is a small site, and once a dependency of Yaxchilan. All of the structures seem to have been built in the period from about 580–800 AD. Bonampak contains several medium-sized temples around a plaza, along with a few carved stelae, but is famous for the murals in one of the buildings. The Temple of the Murals, or Structure 1, is a long narrow building with three rooms atop a low-stepped pyramid base. The interior walls preserve the finest examples of Classic Maya painting, otherwise known only from pottery and occasional small faded fragments. Over the years rainwater has seeped into the plaster of the roof in such a way as to cover the interior walls with a layer of slightly transparent calcium carbonate. These murals first came to modern attention in 1946, when Lacandon Maya who lived in the region showed photographer Giles Healey a small temple whose three rooms house paintings that cover all surfaces. Shortly after Healey's discovery the CIW sent an expedition to Bonampak. The walls were coated with kerosene which made the layer over the paintings temporarily transparent, then the murals were

extensively and completely photographed and duplicate paintings were made by two different artists. The paintings date from 790 A.D. and were made as frescos, with no seams in the plaster indicating that each room was painted in a single session during the short time that the plaster was moist. The three rooms show a series of actual events with great realism. The first shows robing of priests and nobles, a ceremony to mark a child as a noble heir, musicians playing wooden trumpets, drums, and other instruments, and nobles conferring in discussion. The second room shows a war scene, with prisoners taken, and then the prisoners, with ritually bleeding fingers, seated before a richly-attired Chaan Muan, the Lord of Bonampak. It is usually presumed that the prisoners are being prepared for human sacrifice, though this is not actually shown in the murals. The third room shows a ceremony with dancers in fine costumes wearing masks of gods, and the ruler and his family stick needles into their tongues in ritual bloodletting. The accompanying hieroglyphic text dates the scene and gives the names of the principal participants. From at least the 400s AD onward, lords at Bonampak skirmished with those from Yaxchilan, 26 km

away; but by the 700s the royal families at the two cities had achieved *détente*. By A.D. 800, when the paintings were completed, the region was suffering from deforestation, exhausted farmland, and overpopulation. Some cities were burned to the ground; others were simply abandoned. By A.D. 900 the forest had begun to reclaim the area. Concerned about the continued deterioration of the murals in the rainforest environment, Mary Miller, a professor of the History of Art at Yale University, established the Bonampak Documentation Project in 1995 to record every detail of the murals before they disappeared. One important goal of the project was to use infrared film to document the paintings, which reveals details invisible to the naked eye. Team members directed and assisted photographers at the site, recording every scrap of paint within the three narrow chambers in three formats: color film, photographic infrared, and video infrared.

19.1.

KARL RUPPERT

Bonampak Expedition

YB 46:177–179, 1947

Early in 1946 Mr. Giles G. Healey, employed by the United Fruit Company to make a photographic record of the Maya, past and present, was in the eastern part of the state of Chiapas, Mexico, filming some groups of Lacandon Indians, and was directed by them to the site of Bonampak. Here he noted some remarkably well preserved paintings on the walls and vaults of the only stranding three chambered building.

On his return from the bush Mr. Healey reported the find to the Chairman of the Division, who at once arranged for Sr. Antonio Tejeda, Division artist, to go to Bonampak. In July Mr. Healey and Sr. Tejeda spent five days at the site. The paintings, as shown by the sketches made at that time, were so remarkable and so important that it was considered imperative to send an expedition for their complete recording.

In the winter of 1947 such an expedition was undertaken, financed by the United Fruit Company and directed by Carnegie Institution of Washington. Personnel included: Karl Ruppert, in charge; Gustav Strömsvik, engineer; J. Eric S. Thompson, epigrapher; Antonio Tejeda, artist (all of Carnegie Institution); Giles G. Healey, photographer, United Fruit Company; and Agustín Villagra, artist, Instituto Nacional de Antropología e Historia, México.

Mr. Strömsvik reached Bonampak January 31, having gone ahead to arrange transportation and establish camp. Messrs. Healey and Thompson arrived February 15 and returned to Tenosique February 28. Mr. Thompson returning to the [United] States, and Mr. Healey again leaving for the ruins on March 6. The remainder of the party, proceeding by plane to Agua Azul on the Usumacinta River and thence by mules, reached the site March 17.

Bonampak lies about 25 leagues south and slightly east of the ruins of Yaxchilán at an elevation of 400 m. In this area Mr. Healey has found a number of previously unreported ruins. The site is relatively small, compact, and carefully laid out, with a main plaza measuring 90 m by 110 m and surrounded on three sides by low mounds. The fourth side is defined by a natural hill, 43 m high, artificially terraced, from which, from plaza level, a broad flight of six steps rises to a wide landing on which were found Stelae 2 and 3 and their associated altars. From this landing the stairway, now wider by 12 m, continues to a second landing on which are seen two standing buildings. Building 1, containing the wall paintings, is of three rooms; the other is a single chambered structure. A third platform or landing 14 m higher supports six standing buildings, each with a single chamber. On top of the hill reached by a well defined stairway are a number of artificial mounds formed by the collapse of structures. Though the eight standing buildings are in a surprisingly good state of preservation, large trees growing on the roofs will hasten their disintegration.

The buildings in most cases rise from a simple plinth. The lower wall zones are plain; the masonry is of blocks with some slabs. The upper zones are faced with small, rectangular slabs, rise with a batter, and often show traces of stucco decoration. Only one structure has roof ornamentation; it consists of a perforated roof comb formed by a series of seven transverse walls, 4 m in height. The vaults show much variation: simple soffit slopes, interrupted slopes, and stepped. The lintels of all standing buildings are of stone, four of them sculptured.

Only one of the five stelae found in the plaza is sculptured. This monument, now broken, had a height of 5 m, width of 2.6 m, and thickness of 20 cm. It carries an Initial Series date of 9.17.?.?.? and is further sculptured with a single human figure. Also in the plaza are a number of plain altars, circular and rectangular, one of the latter resting on short wedge-shaped legs. A crudely carved jaguar figure, 2.2 m long, lies in the northeast sector of the plaza unassociated with any structure. The two stelae and two altars on the first landing of the terraced hillside are beautifully sculptured. One of the buildings on the upper landing con-

tains a plain stela; inside four buildings are plain, slightly tapering, columnar altars.

Building 1, with three chambers, contains the wall paintings. The building has an over-all length of 16.5 m and width of 4.1 m. Its exterior construction is similar to that of other buildings at the site. In the upper zone there remain traces of stucco decoration and niches containing seated figures. A wide bench is built against the end and back walls of each room; from an offset at the spring line, the vault rises in a slope with a single interruption. Beam holes, in pairs, are seen at two levels.

The recording of the paintings in Room 1 constituted the major project of the expedition. The condition in which the paintings were found and the preparation necessary before they could be copied is described by Sr. Tejeda:

Growing out of the top of the building were great trees whose roots pierced the masonry. In some parts where they have rotted owing to the action of time or to the separation of the stones, the roots have permitted a constant infiltration of water, which has deposited on the stucco walls a calcareous sediment that in some places is so thick that it is impossible to perceive what kind of decoration existed. This destructive action is evidenced sometimes by petrified bubbles, and sometimes by a calcareous layer, just as though the walls had been painted white. In some places the infiltration is so constant that it has washed away the paintings, making recovery impossible. The humidity has also favored the growth of fungus, green and black. A factor that has contributed greatly to the destruction, especially where the walls are vertical as are the divisions between rooms, is the droppings of a great many bats which have found a comfortable lodging in the upper part of the vault. Finally, it is believed that the most dangerous element of destruction is the capillary roots that have entered between the wall proper and the plaster surface that carries the paintings. The damage may be seen in places where the roots have wedged out and displaced the painted stucco, now lying on the floor, almost pulverized.

Sr. Villagra, who also made copies of the wall paintings, and Sr. Tejeda began the long and tedious task of cleaning the walls before starting to draw. To obtain greater transparency of the calcareous coating, once we had removed the thickest part, we applied water, but succeeded only in vaguely enlivening the colors. It occurred to Sr. Tejeda to try kerosene, and the result was a great success, as it was possible to observe in the paintings details which previously were not known to exist. The kerosene is applied with a brush, and the action endures

approximately eight or nine hours, after which it disappears by absorption and volatilization. It does not hurt the colors, and serves temporarily to impede the formation of fungus.

Never before had such a wealth of Maya wall paintings been available, nor had anything been found comparable in subject matter, detail, and execution. On the walls and vault of this one room 34 human figures are portrayed. In the center of the back wall are three figures wearing elaborate costumes and ornate headdresses. To their left is a group of musicians, some blowing long trumpets, some carrying gourd rattles, others carrying turtle shells which are struck or rasped with a forked stick. One man stands behind a vertical drum with a skin stretched over the upper end. The figures to the right bring offerings or are in positions of adoration. The first band on the vault is of hieroglyphs and groups of human figures; above this, on the vault and capstones, are large bold masks.

In the time spent at the site the artists were able to copy the paintings in only one chamber. Although those in the middle room were not recorded, some of the scenes, such as that in which blood is seen dripping from the ends of men's fingers, or those showing processions and probably battles, are of such interest and excellent draftsmanship that their value is equal to if not greater than that of the paintings copied this past season.

19.2.

GUSTAV STRÖMSVIK
Bonampak Expedition

YB 47:211–213, 1948

A report on the 1947 expedition to the ruins of Bonampak, under the direction of Mr. Karl Ruppert, of Carnegie Institution, financed by the United Fruit Company, and participated in by the National Institute of Anthropology and History of Mexico, appears in *Year Book* 46. The primary objective of that expedition was to copy the extraordinary mural paintings discovered there by Mr. Giles G. Healey in 1946. Owing to various delays and transportation difficulties, the murals in only one of the three decorated rooms were completely copied, but these proved to be so magnificent and so important that the United Fruit Company continued

its support in 1948, thus making it possible to finish copying the paintings and to obtain additional data on the site. The 1948 expedition was organized by Sr. Antonio Tejeda F., artist, and Mr. Gustav Strömsvik, archaeologist, both of the Carnegie Institution. Sr. Agustín Villagra, of the National Institute of Anthropology and History, again participated, and, to insure completion of the work, the services of Sr. Hipólito Sánchez, of the Archaeological Museum in Campeche, were obtained.

The earlier expedition had encountered great difficulties in procuring mule transportation to the ruins; this year, with chicle exploitation of the region stopped, mules were virtually unobtainable. In view of the possibility that equipment and supplies might have to be transported on the backs of men, impediments were cut down to an absolute minimum, in both weight and volume.

Equipment and supplies were assembled in Mérida and shipped by rail to Tenosique. On March 1, 1948, Tejeda joined Strömsvik in Mérida, and the next day they proceeded by train to Campeche, where they were met by Villagra and Sánchez. Ways and means for reaching the ruins were discussed. Four men were hired to carry the packs from Santa Clara chicle station to the ruins, should that prove necessary. Santa Clara was chosen as point of entry because it is the landing field nearest the ruins and the trail is fairly good.

On March 5 the expedition took the train from Campeche to Tenosique, there being no regular air service over that route. At Tenosique, through connections and friendships made last season, 12 mules and two muleteers fortunately were obtained and sent overland, via Piedras Negras, to Santa Clara. On March 12 a bi-motored plane was chartered at Tenosique to fly the staff and equipment to Santa Clara; in the evening of the same day the mules and boys arrived at the chicle station. After a day's rest, the expedition got under way into the jungle, the men taking turns walking and riding. The trail was much overgrown and very difficult to follow, and several times it was lost. In spite of these delays, the ruins were reached in two and a half days without serious incidents.

On the trail to the ruins, numerous mounds were noticed, but no cut stones or sculpture. Such remains occur some 300 m south of the chicle camp at Santa Clara, by the Lacanhá River, and at an abandoned chicle camp called Moguel, about halfway between Lacanhá and Bonampak.

At the ruins, the area in front of Building 1, which had been cleared the previous year, was completely covered by lush vegetation, but the thatch house built last season would still give shelter. The artists immediately set to work at preparations for copying the re-

maining paintings. Getting the camp settled, the supplies protected against occasional heavy showers, and camp routine established, came first. Afterward, time was spent in helping the artists and in preparing the walls for copying. Scaffolding had to be built of materials at hand; the kerosene lamps used for illumination created so much heat and carbon monoxide in the rooms that a fan had to be constructed to force in fresh air to enable the artists to work. Owing to transportation difficulties, a very limited supply of canned goods and meats had been brought along, but the neighboring Lacandon Indians supplied some sweet potatoes, plantains, and green corn. One of our workmen turned out to be a good hunter, and with our shotgun supplied the necessary meats.

When time permitted, notes were made of further details to complete the Bonampak map. Numerous excavations were made in courts and by stairways to find ceramic specimens, but in vain. During the interval since last season, the major part of the complicated roof ornamentation of Building 4 had fallen, but all details are preserved in Ruppert's careful architectural notes of the site.

The work of copying the paintings in the remaining two rooms of Building 1 progressed according to a carefully calculated program and was completed during the six weeks allotted for the task. According to agreement made beforehand, the expedition was met by a plane at the Santa Clara field April 24. The expedition had completed its task.

19.3.

ANTONIO TEJEDA F.

Bonampak Expedition

YB 47:213–214, 1948

Until the discovery of the Bonampak murals, nothing had led us to suspect the great technical ability and the extraordinary mastery of drawing and of composition possessed by the Maya painters of the Classic period.

The method used in producing the murals was apparently as follows. On the still moist plaster the artist drew the entire composition in sepia color, which in some instances is blood red, perhaps owing to the action of time. There is no doubt that the design outline and major color backgrounds were painted di-

rectly on the fresh wall surface, because fallen pieces of the paintings show the pigment deeply embedded in the plaster. The relatively large compositions, covering an entire wall surface, were presumably accomplished in this fresco technique by laying the final coat of plaster on one section of wall at a time, and possibly by the use of assistants to apply color after the composition had been rapidly outlined. In some parts of the compositions corrections may clearly be observed, left unchanged by the artist rather than risk damaging the wall. In order to intensify color for shading, to obtain different tones, or to strengthen and bring out details, the artist used pigments mixed with some unknown adhesive, which did not materially affect the permanence of the colors. The superimposition of colors in certain areas is revealed by the fallen pieces referred to above. The entire technique, fresco-tempera, is curiously like that of the Italian Renaissance. Only mineral paints seem to have been employed. Their selection and preparation were astonishingly skillful, as they have retained their tone and brilliance through the centuries, in spite of the most adverse climatic conditions.

The paintings of Rooms 2 and 3 have now been faithfully copied; those of Room 1 were copied in 1947. Those of each chamber are independent in regard to composition and descriptive action of the scenes, a unit of arrangement and subject matter, but all three paintings form a most harmonious total composition. Each must be studied by itself, however, in order to appreciate the resourcefulness with which its elements have been fitted to the available spaces, and the skill with which individual figures and groups have been balanced.

The paintings of Room 2 represent the highest plane of artistic conception. On one wall there is depicted a stirring scene of battle. Another part of the room shows the torture of prisoners. A very high place in the history of art must be granted to these renderings which, for balance, harmony, dynamic action, and the expression of ferocity, triumph, suffering have seldom been surpassed. One figure, that of a sacrificed captive, exhibits a knowledge of foreshortening that is truly marvelous.

In Room 3, as in Room 1, are depicted scenes of ceremony, including winged figures with rich and elaborate headdresses. As spectators there are several priests wearing long white robes similar to those of persons in Room 1. There are also several women seated on a dais, at whose base is another woman holding a child in her arms. These women and the priests form groups of great interest and charm.

Many of the glyphs found in Rooms 2 and 3 have suffered severely, and their decipherment will be difficult. It seems that the artists of Bonampak were more concerned with the depiction of events, with action, and with the magnificent costumes of individuals than with recording of chronological data.

The paintings in Room 1, copied last year, remain in excellent condition, and the cleaning of the walls permits them to be seen more clearly. Those of Rooms 2 and 3 are less well preserved because of the heavy calcareous coating deposited on their surfaces, the filtering of water through the walls, and the stains produced by fungi and bat droppings.

During the stay at Bonampak, drawings were made of the sculptured lintels of the doorways opening into the three painted rooms. These are in low relief, each depicting a warrior with a prisoner. They had once been painted in the same polychrome style as the murals. Only a few patches of the colors are left, but these may make possible color restorations of the carvings.

The National Institute of Anthropology and History faces a very difficult problem in the preservation of the wonderful paintings at Bonampak. Some sections of the stucco background, which has an approximate thickness of one centimeter, have loosened from the walls because of the humidity. The open spaces thus formed collect moisture and are used as nesting places by insects. This is causing parts of the murals to fall, and such areas require prompt attention. Attempt was made by the 1948 expedition to clean the building as much as possible. All vegetation was removed in order to halt the destruction caused by roots, many of which have penetrated the walls and produced cracks and passages which allow water to enter during the downpours of the rainy season.

20.0. YAXCHILÁN

Yaxchilán, known for the large quantity of excellent sculpture, was a large Classic period center, and the dominant power of the Usumacinta area. It dominated such smaller sites as Bonampak, and was long allied with Piedras Negras, and at least for a time, with Tikal. It was a rival of Palenque, with which Yaxchilán warred. Yat-Balam, founder of a long dynasty, took the throne on 2 August, 320 when Yaxchilán was a minor site. The city-state grew to a regional capital and the dynasty lasted into the early ninth century. Yaxchilán had its greatest power during the long reign of King Shield Jaguar II, who died in his 90s in 742. The first published mention of the site seems to have been a brief mention by Juan Galindo in 1833. Edwin Rockstroh visited the site in 1881 and published short account. Alfred Maudslay and Désiré Charnay arrived here within days of each other in 1882, and they published more detailed accounts of the ruins with drawings and photographs. Teobert Maler visited the site repeatedly from 1897 to 1900, and published a detailed two volume description of Yaxchilán and nearby sites in 1903. In 1931 Morley led a CIW expedition to Yaxchilán, mapped the site and discovered more

monuments. The Mexican Instituto Nacional de Antropología e Historia (INAH) conducted archeological research at Yaxchilán in the early 1970s, again in 1983, during the early 1990s.

20.1.

SYLVANUS G. MORLEY

*Report of the Yaxchilán Expedition*YB 30:132–139, 1931

On March 22, just after the close of the Chichén Itzá Conference, the Yaxchilán Expedition left for the State

of Chiapas. The staff consisted of Dr. Morley in charge; Mr. Ruppert, archaeologist; Mr. Bolles, surveyor and engineer; Dr. Dwight M. Rife, physician and chairman; Mrs. Morley, in charge of the commissary, and Mr. F. K. Rhoads, camp assistant.

After a day at Mérida for the purchase of supplies, the Expedition left for Campeche on March 24. Through the kindness of Don Salustino Abreú, of Campeche, his boat, the *Nueva Esperanza*, a 50-ton schooner with auxiliary engine was in readiness and late the same afternoon the Expedition left Campeche for Ciudad del Carmen at the mouth of the Usumacinta River.

The *Nueva Esperanza* stopped at Ciudad del Carmen for several hours to permit the making of the necessary financial arrangements for the long trip up-river and into the interior. Mr. Leslie Moore, manager of the Phoebe Hearst Estate in Campeche, kindly acted as banker, supplying a certificate of deposit against which checks were issued throughout the course of the expedition, thus obviating the necessity of carrying large amounts of heavy silver into the interior. This method proved highly successful and is to be recommended for other scientific expeditions operating in the remote and inaccessible regions of the upper Usumacinta Valley.

Early the following morning the *Nueva Esperanza* reached the hacienda of Chablé on the east bank of the Usumacinta River in the State of Tabasco and the same afternoon arrived at Monte Cristo on the west bank, the starting-point for the ruins of Palenque.

Through the kindness of Señor Lic. Don Tomas Garrido, Governor of Tabasco, a Ford truck was placed at the Expedition's disposal for making the trip to Palenque. This truck with a reserve supply of gasoline, there are no filling stations in the Tabasco hinterland, left Monte Cristo at 4:15 in the morning of March 27, and reached the modern village of Santo Domingo Palenque, not to be confounded with the ruins of Palenque, at 8:30 A.M.

From the village to the ruins, it is necessary to proceed on foot or horseback through the forest for another 10 km. The trail gradually climbs over ever-rising foothills until the Río Chacamax is crossed, beyond which there is a final steep ascent to the bench where the ancient city of Palenque was built.

After a hasty examination of this important Old Empire site, the Expedition staff was obliged to return to the village of Palenque, and thence by truck back to Monte Cristo in order to make connections with the *Nueva Esperanza* which was leaving the same night for the village of Tenosique, at the head of steam navigation on the Usumacinta River and the point at which mule trains with supplies for the mahogany camps high up the river leave for the interior.

The Expedition reached Tenosique on the afternoon of March 28. Don Francisco Villanueva, who had acted on former expeditions as the Institution's resident agent at Tenosique, had secured a house in the village where the equipment and supplies were stored and had already arranged for mules to transport the staff and outfit from Tenosique to Salvamento, a half-day's journey below Yaxchilán by river.

Sunday, March 29, was spent in consultation with the chief *arriero* (muleteer), Rosendo Esparza, who had taken the Thirteenth Central American Expedition to Piedras Negras in 1929, about the arrangement of the packs. It was decided that 21 cargo animals would be required and 12 saddle animals, six for the staff, two for the camp assistants, and four for the *arrieros*.

The first half of the Expedition, consisting of the staff, two camp assistants and two *arrieros* with nine pack animals, left Tenosique on the morning of Monday, March 30, the second half leaving the following morning.

The first half of the Expedition reached the ruins of Piedras Negras, now being excavated by the University of Pennsylvania, the next evening, March 31. Dr. J. Alden Mason in charge of the University of Pennsylvania Expedition had an excellent camp on the east bank of the Usumacinta River, just north of the ruins. Comfortable houses of split bamboo with thatched roofs had been built both for his staff and the laborers, as well as store-rooms, company store, photographic dark-room, corrals for the mules, and even a vegetable garden.

The Yaxchilán Expedition remained at Piedras Negras for two days. Dr. Mason, Messrs. Satterthwaite and Egan-Wyer of the University of Pennsylvania staff showed them the excavations, the new monuments found and the material recovered. It was decided to stop at Piedras Negras for several days on the return from Yaxchilán early in May, nearer the end of the when excavations there would be more advanced.

The first half of the Expedition left Piedras Negras for Salvamento on April 3, the second half having already passed through Piedras Negras, en route to Salvamento, the previous day. Both sections reached Salvamento within an hour of each other late the following afternoon, April 4.

Arrangements were made with Ulises Cruz, the newly appointed custodian of the ruins of Yaxchilán, to transport the staff and outfit in two dugout canoes the remaining half-day's journey by river from Salvamento upstream to Yaxchilán.

That evening camp was made on the river shore at Salvamento, hammocks being swung and cots being placed between poles driven into the sand, from which the absolutely indispensable mosquito-bars were hung. The next morning, Easter Sunday, April 5, the

Expedition embarked in two dugout canoes and reached Yaxchilán, the goal of all this arduous travel, about two o'clock, in the afternoon, just 14 days after leaving Chichén Itzá.

The ruins of Yaxchilán lie in an enormous omega-shaped bend on the west bank of the Usumacinta River in the State of Chiapas, Mexico. Almost opposite the middle of this site there are the remains of a masonry construction in the river, now reduced to a roughly conical mass. This is near the east bank but except at lowest water is always separated there from, while at high water it almost entirely disappears. The buildings and terraces of the city are so completely overgrown with a vast tropical forest that no vestige of them appears from the river, so that this conical mound of fallen masonry is an excellent marker for the location of the site.

The Expedition spent 29 days at the site. Camp was made on a bench along the river bank just below Structure 16. The underbrush was cleared and three tarpaulins were stretched to accommodate the hammocks and cots of the members of the party. Thatched shelters without sides were also built to protect the food supplies and general stores from sun and rain. Another thatched shelter, also without sides, was built for the mess.

The scientific activities at Yaxchilán may be divided into three main groups: 1. Epigraphic work consisting of drawings, photographs, and descriptions of the hieroglyphic inscriptions by the writer; 2. Architectural studies, ground-plans, descriptions, etc., by Mr. Ruppert; and, 3. General map of the site by Mr. Bolles and Dr. Rife.

During exploration incident to the architectural studies and the mapping, Messrs. Ruppert and Bolles discovered a considerable number of new sculptured monuments, stelae, altars, lintels, inscribed steps, etc., a new ballcourt, and two new groups of associated structures. The new monumental material may be summarized as follows: 12 sculptured stelae, 13 sculptured altars, eight sculptured lintels, five sculptured door steps.

From this new material there were deciphered 11 new Initial Series and two new Period Ending dates as follows [in Table 20.1.1].

Probably the most important chronological contribution was the discovery by Mr. Ruppert on May 2 of the earliest known contemporaneous monument in the Usumacinta Valley, namely Stela 27 dating from 9.4.0.0.0.

The stylistic criteria of Stela 27 are in satisfactory agreement with this early date. The relief is low and the execution inferior; the proportions of the human figure are poor and the position stiff and awkward; finally, the monument itself is very small, the sculptured

Table 20.1.1. Calendrical Decipherments, Yaxchilan.

<i>Initial Series</i>		
Stela 27 (Str. 9)	9.4.0.0.0	13 Ahau 18 Yax
Stela 14 (Str. 44)	9.4.8.8.15	13 Men 13 Kayab
Lintel 48 (Str. 14)	9.4.11.8.16	2 Cib 19 Pax
Altar 4 (Str. 39)	9.16.1.0.0	11 Ahau 8 Tzec (?)
Altar 5 (Str. 39)	9.?.	?
Altar 6 (Str. 39)	9.?.	?
Altar 7 (Str. 23)	9.14.15.0.0	11 Ahau 18 Zac
Altar 9 (Str. 33)	9.16.0.0.0	2 Ahau 13 Tzec (?)
Altar 12 (near Stela 1)	9.?.	?
Altar 13 (Str. 40)	9.0.0.0.0	8 Ahau 13 Ceh
Altar 14 (Str. 40)	9.16.1.0.0	11 Ahau 8 Tzec
<i>Period Endings</i>		
Lintel 52 (Str. 55)	9.16.15.0.0	7 Ahau 18 Pop
Lintel 54 (Str. 54)	9.16.5.0.0	8 Ahau 8 Zotz

ured panel being only 1.37 m high by 86 cm wide. The earliest previously known monument found in the Usumacinta Valley is Stela 30 at Piedras Negras dating from 9.5.0.0.0., that is, 1 katun (19.71 years) earlier.¹

Of scarcely less importance than Stela 27, and of almost equal antiquity is Lintel 48, discovered by Mr. Ruppert on April 15 in Structure 12. The Austrian explorer Teobert Maler, who visited Yaxchilán on several occasions in behalf of the Peabody Museum of Harvard University (Maler 1903), described this building as having had four doorways in its southeastern façade, spanned by lintels to which he gave the numbers 34, 35,² 36 and 37 (Maler 1903:133, 134). Mr. Ruppert made a new ground-plan of this building and discovered that the southeastern façade originally had been pierced by seven doorways. Further façade measurements indicated that Maler had failed to locate the second, third, and seventh doorways facing the building. Excavation in front of these doorways brought to light the three sculptured lintels which had originally spanned them, to which the numbers 47, 48 and 49 were given. Owing to the fact that these had fallen with their sculptured faces down, the relief is in a perfect state preservation.

The most important of the three lintels, indeed of all seven in this building, is the new Lintel 48 which presents a very unusual full figure Initial Series, recording the date 9.4.11.8.1, 2 Cib 19 Pax, which apparently is either the dedicatory date of this building, or very close thereto.

The glyphs are in a magnificent state of preservation, much of the red pigment, with which the lintel originally had been painted, still adhering to the relief. All of the period glyphs except the one for the tun-sign are represented by full-figure forms, the earliest example of a full-figure Initial Series yet found. The baktun sign is represented by a vulture (?); the katun

sign by a parrot (?); the uinal-sign by a frog and the kin-sign by a monkey. The Supplementary Series and month-part corresponding to this Initial Series are recorded on Lintel 47 over the next doorway to the left facing the building. It was the correct decipherment of the latter which alone made possible the reading of this date.

By the same method, façade, doorway and inter-doorway measurements, Mr. Ruppert located the position of another new doorway Structure 13 and excavation in the façade débris in front of this brought to light a fourth sculptural lintel, no. 50, apparently without a date.

A third monument was found at Yaxchilán during the current season presenting a Katun 4 date, namely Stela 14, recording the Initial Series 9.4.8.8.15, 13 Men 13 Kayab. The latter half of the inscription on Stela 14 has not been found, but the stylistic evidence clearly indicates that this monument was erected at a much later period than Katun 4, probably at least two centuries later than the Initial Series date.

A similar case is presented by the inscription on the tablet in the Temple of the Inscriptions at Palenque, where although the inscription begins with the Initial Series 9.4.0.0.0, 13 Ahau 18 Yax, the contemporaneous date of this tablet is 9.13.0.0.0, 8 Ahau 8 Uo, nearly two centuries later.

Judging from the style of Stela 14 it would seem to have been executed during the Great Period of the Old Empire (after 9.15.0.0.0), that is more than two centuries later than its Initial Series.

It would seem from the evidence afforded by the following five earliest known Initial Series in the Usumacinta Valley of which the last two, however, are not contemporaneous, that this western part of the Old Empire probably reached the point of making records on stone about 9.4.0.0.0:

1. Yaxchilán, Stela 27, 9.4.0.0.0
2. Yaxchilán, Lintel 48, 9.4.11.8.16
3. Piedras Negras, Stela 30, 9.5.0.0.0
4. Palenque, Temple, Ins., 9.4.0.0.0 (not contemporaneous)
5. Yaxchilán, Stela 14, 9.4.8.8.15 (not contemporaneous)

Yaxchilán, Piedras Negras, and Palenque are the three largest cities of the Usumacinta Valley, and it hardly appears to be the result of accident that the earliest contemporaneous dates of the first two are 9.4.0.0.0 and 9.5.0.0.0 respectively and that the long text in the Temple of the Inscriptions at Palenque, which presents a series of 10 consecutive katuns ending 9.13.0.0.0, begins with the same date as the earliest contemporaneous date at Yaxchilán, that is, 9.4.0.0.0.

Possibly the early Initial Series 9.4.8.8.15, on the much later Stela 14 at Yaxchilán, may be a later

memorialization of an earlier date, important in the early history of the city. The new evidence secured during the current field season not only corroborates the previously known evidence from Piedras Negras and Palenque touching on the point, but also tends to indicate that the cities of the Usumacinta Valley reached the point of committing their records to stone about 9.4.0.0.0.

The most important date at Yaxchilán, Dr. Morley was able to show as a result of his first visit to this site in 1914, was 9.16.1.0.0, recorded twice on Stela 11, each time as an Initial Series and as a Period Ending on Stela 12 and Lintel 1. This season the same date was found as an Initial Series on two different altars, nos. 4 and 14, making six occurrences of this date in all.

Mr. Bolles discovered a new building, Structure 55, at the new Southeast Group, the north façade of which was pierced by three doorways. Excavating in the débris just in front of these doorways, three magnificently sculptured lintels were found, nos. 51, 52 and 53. The one over the middle and probably the most important doorway records the date 9.16.15.0.0, 7 Ahau 18 Pop, doubtless the dedicatory date of this building.

Several days before leaving, Mr. Bolles discovered another building just east of Structure 55, namely Structure 54, which also seems to have had three doorways in its north façade. The entire front of this building had collapsed and the position of the two end doorways was not apparent on surface of the mound. The middle doorway, however, was located, and excavation in the débris in front of this brought to light the eighth sculptured lintel found by the Yaxchilán Expedition, Lintel 54. The date recorded on Lintel 54 is 9.16.5.0.0, 8 Ahau 8 Zotz, which probably indicates the dedicatory date of this building.

Unfortunately time was lacking to locate the two remaining lintels which had originally spanned the two end doorways of this building, but these are almost certainly sculptured like those over the end doorways in the nearby Structure 55, and a few days' excavation would doubtless bring them both to light.

It is becoming possible, because of these recent discoveries, to begin piecing together the chronological record at Yaxchilán. For example, the four hotuns of Katun 17 were commemorated by the dedication of the following period markers:

- 9.16. 5.0.0 by the dedication of Structure 54 (Lintel 54)
- 9.16.10.0.0 by the dedication of Stela 1
- 9.16.15.0.0 by the dedication of Structure 55 (Lintel 52)
- 9.17. 0.0.0 by the dedication of Structure 10 (Lintel 31)

Doubtless further excavation will disclose other structures and monuments which will fill in still existing lacunae in the sequence of the period markers at this site.

Possibly the three most important architectural discoveries made by Mr. Ruppert were: 1. The five sculptured circular stones in the floor of the old ballcourt (Structure 14), probably used as markers for placing the ball in play, defining the limits of play; 2. The five sculptured steps *in situ* before the three doorways of Structure 44; 3. The nine small stucco figures seated on a low bench in the southeastern chamber of Structure 40.

Excavating in the floor of the new ballcourt, Mr. Ruppert found three sculptured, circular stones along the middle longitudinal axis of the court, one at each end and the other at the center of the court. Two other similar sculptured, circular stones were found one on each of the two platforms along the sides of the court, also in line with the central stone. As noted above, these may have been used as base stones for putting the ball in play, and the two end ones possibly as defining the limits of play. At Chichén Itzá lines of cut stone let in the floors of the courts at both the open ends seem to have served the same purpose.

Acting on this hint, Dr. Mason excavated in the two ballcourts at Piedras Negras and found five plain (that is, not sculptured, dressed, circular stones in the same positions in the southern one (Structure X-XI).

It seems probable that the three sculptured, circular stones found in line between two mounds at Lubaantún (Structure A-B) by Merwin of the Peabody Museum Expedition of 1915,³ and the one found between two at Cancuen (Structure B-1-B-II) by the First Central American Expedition also in 1915 [Chapter 1.4], were in each case found in ballcourts.

In 1900 Maler found in front of Structure 44 a large sculptured slab, neither stela nor lintel, inscribed with glyphs both on its top and front face, which he calls a Sacrificial Altar.

In excavating the three doorways of this same building, Mr. Ruppert found in the southeastern doorway two similar slabs *in situ*, so located as to indicate that they had been steps leading to the doorway. He found two similar slabs in the northwestern doorway, also serving as steps, but in the middle doorway only, the lower slab or step is *in situ*.

It became apparent that Maler's so-called Sacrificial Altar found by him in 1900 was in reality the missing, upper step of the middle doorway, which must have been removed in ancient times from this position to the front edge of the terrace on which Structure 44 stands, since the other five inscribed steps were all found deeply buried under masses of fallen façade débris.

The single Initial Series recorded on these six steps, 9.12.8.14.1, 12 Imix 4 Pop, is found on the upper step in the middle doorway, that is on the slab which had been removed in ancient times to the edge of the terrace in front of Structure 44. There are at least nine Calendar Round dates, however, with accompanying Secondary Series numbers recorded on the other five steps. It is hoped further study will establish the connection of all of these with the Initial Series.

In the southeastern chamber of Structure 40, Mr. Ruppert found the remains of nine small, anthropomorphic figures, made of stucco, seated in a row on a low bench not more than a foot [31 cm] high running across the back wall. The upper parts of all had been destroyed, but in clearing the floor of débris he came upon the remains of nine pairs of feet and legs *in situ* on the floor, built against the face of this low bench. When complete, even allowing for elaborate feather head-dresses, these seated figures could not have been more than 1.5 feet [46 cm] high.

The number of these seated stucco, anthropomorphic figures forcibly recalls the Nine Gods, the Bolontikú, frequently mentioned in the Books of Chilam Balam, the names of which though unknown, are almost certainly represented by the nine different forms of Glyph G of the Supplementary Series (Thompson 1929). According to Mr. Ralph Roys they are associated with the underworld.

During his cruising through the forest in connection with the survey of the site, as already mentioned, Mr. Bolles found two new and hither unreported groups: 1. The Southeastern Group and 2. The Northwestern Group. The former would seem to have been of considerable importance.

Four of the eight new sculptured lintels, nos. 51, 52, 53 and 54, found during the current season, and four of the 12 new stelae, nos. 24, 25 and 26, and the unsculptured and also unnumbered new stelae southwest of the long chain of low mounds along the river bank, just east of the main group, were found here, and further exploration would certainly bring to light other sculptured monuments, especially sculptured lintels.

No sculptures, or even partially standing buildings, were found a Northwest Group, which was nicknamed "Poverty Hill" because of its apparent lack of interesting features, as compared with the Southeast Group.

The topography at Yaxchilán powerfully coerced architectural assemblage and development. Along the curving river bank, but well above the highest water-level, a practically continuous line of buildings was erected, most of which seem to have faced away from the river, that is, looking toward a series of courts and plazas made on the first bench-level above the river. On the far side of these courts, built on terraces at the

bases of sharply rising hills, there is a second line of buildings curving around the bases, roughly paralleling the river.

The slopes of these hills have been literally made over into an elaborate system of terraces, which rises from the courts on the first bench-level to the hilltops. The summits themselves have, been leveled and each supports a number of buildings: The Northwest Group, the West Acropolis, the Central Acropolis and the South Acropolis. The last is reached by a series of receding stairways, all in the same axis, several hundred feet in height.

When Yaxchilán was occupied, the forest cleared, the succeeding ranges of white stucco buildings rising one behind the other, the terraced hills surmounted by other groups of buildings, the whole crowned by the distant and lofty South Acropolis, the effect must have been magnificent, making this site, because of its superb natural setting, perhaps the most spectacular in the Maya area.

The Expedition left Yaxchilán on May 5, returning by river as far as Piedras Negras, where a second stop of three days was made at the University of Pennsylvania camp. During the Expedition's five-weeks absence up river, remarkable progress had been made. The new road from Piedras Negras to the Pass of San José, 50 km, was finished; the monuments selected for removal to Guatemala and the Museum of the University of Pennsylvania at Philadelphia were being boxed and the excavations had yielded material of first importance. Indeed, Lintel 3 found in Structure 27 may, without exaggeration, be said to be the finest example of an American sculpture yet brought to light. This lintel will be exhibited at the Museum of the University of Pennsylvania this coming year.

The Expedition left Piedras Negras on May 8 and arrived at Tenosique before night, thanks to the new road, the dry season and the cooperation of Don Francisco Villanueva of Tenosique, who had a motor launch waiting at the Pass of San José. On May 10 Ciudad del Carmen was reached.

The next afternoon the motor canoe *Angelita* (Little Angel) was leaving for Campeche. Never was there greater misnomer. In addition to chickens and dogs, which roamed the single open deck at will, two Ford cars lashed crosswise of the boat occupied most of the available deck space; the staff pillowed on the running board of one of these Fords. Campeche was reached the following afternoon (May 11), everybody very much the worse for wear.

The Expedition left Campeche for Mérida the following day, reaching there the same night (May 12). A day's stop was made in Mérida in order that the photographic negatives might immediately be developed, owing to the danger of rapid deterioration from the excessive heat at the close of the dry season.

The next morning the staff left for Chichén Itzá, arriving there at noon after an absence of two days less than eight weeks.

NOTES

1. The date of this monument was deciphered by the Fifth Central American Expedition on May 28, 1921, [Chapter 1.9].

2. This lintel was removed to the British Museum by A. P. Maudslay in the eighties of the last century (Maudslay 1889-1902:2:43).

3. These three stones are now in the Peabody Museum, Harvard University, Cambridge, MA.

21.0. EL SALVADOR

21.1.

JOHN M. DIMICK

Salvador

YB 40:298–300, 1941

During the past field season, Mr. Dimick, assisted by Mr. Stanley H. Boggs, continued the intensive study of the great archaeological site of Campana San Andrés. The ruins are situated 32 km northwest of San Salvador in the fertile, bowl-shaped, and mountain-fringed valley of the Río Sucio. Although thorough exploration has not been undertaken, mounds are known to be scattered more or less thickly over the valley floor, an area approximately 48 square miles [124.3 sq km]. The most imposing group, perhaps the religious and administrative center of the entire aboriginal settlement, lies near the middle of the valley on the west bank of the Sucio. Here excavations have been carried out with the generous permission of Don Fratsco Dueñas, the proprietor, who did everything possible to facilitate the work.

The principal group consists of a great plaza roughly 200 m north to south and 140 m east to west, surrounded on three sides by mounds of various dimensions and on the south by an elevated court (over 6 m above the plaza) which in turn, is partially en-

closed by ruined structures. The largest of the latter, Structure 1, almost closes the south side of the elevated court, and Structures 2, 3, and 4 are in alignment along its eastern edge. Small excavations were made for pottery and architectural details throughout the group, but the greater part of the expedition's time was spent in careful exploration of Structures 1, 2, 3, and 4, and one mound, (Structure 8) located on the valley floor just south of the southeast corner of the elevated court.

The excavations have disclosed evidence of aboriginal human occupation over a long, but as yet undetermined, period of time. The earliest remains in the form of pottery and artifacts, were found in the upper 50 cm of a layer of soil forming an early valley floor. This occupational level was covered by a 25 cm layer of sterile volcanic ash. Subsequently, the development of the principal group took place. The earlier stages of the growth of the elevated court are indicated at present only by plastered floors encountered above the ash layer and by a stairway in Structure 1. The floors were

exposed by a deep test pit in the center of the court; the stairway by a trench into the lower part of Structure 1. Well above the early court floors another floor was found, upon which were built the imposing pyramidal Structures 1, 2, 3 and 4. That the pyramids were crowned by temples may be postulated, although positive evidence is still lacking. One of the outstanding architectural features of Campana San Andrés is the fact that, with a few exceptions to be mentioned later, the pyramids and court foundations are entirely of mold-made adobe blocks averaging in size 62 by 24 by 17 cm. Laid carefully in courses, these formed a very solid construction of uniform strength. All exposed surfaces were finished with a smooth coating of excellent lime plaster, which, despite its hardness and good quality, was frequently renewed on court floors and pyramids.

Structure 1 is a nearly equilateral pyramid, which rose in narrow vertical-walled terraces, probably 11 in number, to a height of 15 m. There was a broad projecting stairway on the north side. The pyramid corners and the edges of the terraces and steps are slightly rounded, and the pyramid as a unit is a splendid example of aboriginal architecture. Structures 2, 3, and 4, arranged in an orderly manner along the east side of the court, are very similar to Structure 1 but smaller.

Another building phase followed the erection of Structures 1, 2, 3, and 4. This mainly consisted of raising the whole elevated court level by 4 m to its present height, thus burying the lower terraces and steps of the existing structures. The labor involved in this task may be appreciated more clearly when one considers that at least 600,000 adobe blocks were made by hand and transported by man power to the building site to fill the elevated court, conservatively estimated at 15,000 cubic meters in volume.

Subsequent substructural renovations took place, some merely frontal additions, others burying more of Structures 1, 2, 3, and 4. New forms of decoration were brought into use, balustrades on stairways, terrace moldings modeled in stucco, and possibly sculptured stone heads tenoned in conspicuous place. A number of serpent heads with tenons, and other miscellaneous stone sculptures were found.

A late occupation of the site is suggested by the finding of a stone yoke and fragments of Plumbate pottery in the sloping surface debris of Structure 1.

Structure 8 differs from all others investigated in the main group. It appears to be a rubble-filled platform of two terraces facing west. The terrace walls are faced with well cut, dressed, and fitted blocks of volcanic tufa resembling that used in Copán. The platform underwent at least two building periods. The latest additions in the elevated court, a small rectangular altar attached to the front of Structure 1, and a step added between Structures 1 and 2, are constructed of these cut tufa blocks. Evidence is not sufficient at present to determine whether Structure 3 antedates the use of adobe construction and the late additions represent stone-robbing from Structure 8, or whether the use of cut stone is a late architectural feature post-dating the adobe period.

The excavations have yielded rich sherd material from each architectural accretion, thus integrating more closely the domestic and civic arts of these people. Mr. Boggs remained in Salvador during the off season to devote his time to the study of the ceramic collection.

In pursuance of Mr. Dimick's program of archaeological studies in Salvador, half the force of laborers were employed in work of conservation. Terraces, walls, and floors were coated with cement to prevent erosion by the torrential summer rains. In some instances reconstruction was required to prevent badly cracked walls from falling. Shelters and drains were built where necessary.

Architecturally, Campana San Andrés seems to share more general characteristics with Copán than with other well known sites. Both are located on level valley floors, their main groups centrally placed near a permanent stream. The orientation and assemblage of the principal ruins are similar, each having a great plaza surrounded, on three sides by structures and on the south by a raised, acropolis-like unit supporting massive, pyramidal temple structures. Certain terrace forms, balustraded stairways, well cut block masonry in Structure 8, tenoned, stone heads, and sculptured stone incensarios are a few details these sites have in common. It would seem that Campana San Andrés flourished during the Great, or Acropolis, Period in Copán. Also some connection with Kaminaljuyú may be implied by the finding of mold-made adobes in a tomb at that site. Mr. Boggs' pottery studies and future excavations in Campana San Andrés undoubtedly will show a more widespread connection and a closer association with the sites mentioned.

22.0. GUATEMALA

22.1.

OLIVER G. RICKETSON

*The Present Status of Archaeological
Investigation in Guatemala*

YB 30:112–114, 1931

The termination in 1931 of the sixth season at Uaxactún concludes the second most intensive examination so far carried out of any Maya site, and if it is decided to continue work there for another two seasons, data will in all probability be furnished with which to correlate the time-relations between the five main groups composing this ruin. As a result of the work already accomplished, we can say with absolute assurance that in this, the oldest dated Maya ruin so far discovered, and in presumably the oldest portion of that ruin, no evidence has been obtained to indicate that an other race than the typical brachycephalic Maya ever occupied this region; nor has any evidence been found to indicate esthetic developments, ceramic or otherwise, outside the Maya horizon in its broadest aspects. A marked progressive development within, from early to late, does occur, and there is strong evidence in the lowest, that is, earliest, strata to indicate a long occupancy for that period.

A stage of the Institution's investigation in the so-called "Old Empire" has now been reached in which

the importance of continuing the work at Uaxactún decreases and the importance of linking-up the low-land Maya culture, as typified at Uaxactún, with its parent stem correspondingly increases. I believe that further excavation at Uaxactún will yield only more detailed information in regard to those general features which we know, and that the advancement of scientific knowledge would be better served by a comparison of the data already obtained with that obtainable in some highland Maya site; the evidence of the earliest Uaxactún strata points strongly to the highlands of Guatemala, an area abounding in ruins, few of which have been examined at all, and none intensively. This region is one where, by reason of climatic and economic conditions, important archaeological data may be obtained for the expenditure of less money and less human effort than has been necessary at Uaxactún. The recommendation of any one highland site for intensive examination should not be made without at least one season's reconnaissance. The reconnaissance should include the sinking of pits and their

expansion into trenches wherever indicated; it would certainly result in an important ceramic collection, by means of which the types and stratigraphy of pottery at various sites would be revealed as well as the pottery relations between sites, including, of course, Uaxactún. That there is urgent need for such an investigation, the ruins of Quiriguá alone attest, in this case we have a well-known and accessible ruin, the site of two seasons' excavations, but one in which no test-pit has been sunk to determine the conditions below ground-level. If this is the case in Quiriguá, the state of our knowledge in other sites may well be imagined.

Such information as I have gleaned during a residence in Guatemala for the major portion of the last two years has been culled from casual vendors of pottery to the tourist trade and a few small personal collections; in both of these cases the objects are generally vague when not actually open to serious doubt. A few brief comments may be permitted here.

One of the most productive centers seems to be Santa Cruz [del] Quiché. Presumably the pottery comes from the ruins of Uatatlán and nearby burial mounds. Most of it is primitive in type, distinctly Maya, and on the whole monotonously uniform. Simple plates, tripod vases, and small ollas are not unlike those from Uaxactún, but certain forms decorated with human or grotesque heads in both low and high relief seem to be characteristically highland in origin. Polychrome does not occur, or at least never reaches the market. Crude human figurines of stone, with plain, more or less rectangular incised lines occur in great frequency in all sites from 1 to 6 inches [2.5–15.2 cm] high.

For variation in form and color, and for quantity, the ruins of Chuitinamit on Lake Atitlán are the most productive I have seen. Dr. Kidder and Dr. Roberts visited this site and the latter felt that here much influence must have come from the south, and that it lies too far west to come into the strict Maya sphere.

A small collection from the west coast beyond Retalhuleu, said to have been found in river sand 20 feet below the surface, contained the most primitive pieces I have seen. They differed notably from Maya, as might be expected.

Arevalo and Miraflores, in reality one very large site just outside Guatemala City, are the source of many figurine heads and occasional whole pots, the former bearing a close resemblance to the figurine heads from the lowest at Uaxactún. Conditions here seem ideal for obtaining important stratigraphic data.

Mr. Carlos Luna of the Sociedad de Geografía informs me that very near El Rancho on the Puerto Barrios branch of the railroad, San Agustín Acasaguastlán, is extremely rich in vaulted burial mounds containing many whole pots with each burial. Both he and Sociedad de Geografía are experiencing much diffi-

culty in protecting site from the ravages of commercial pot-hunters. Since it is located in the upper reaches of the Motagua Valley less than 125 miles [201 km] from Quiriguá, it shows strong Maya connections. The only pottery from this site which I have seen is magnificent Maya polychrome and a most interesting green ware not dissimilar from the Plumbate found scatteringly in the Maya area and more frequently in Salvador. As the evidence seems to be that the Maya were a highland people whose culture was destined to extend into the Yucatán peninsula rather than south or west, the location of San Agustín Acasaguastlán in the eastward draining Motagua indicates a site which will undoubtedly repay examination.

Between the Motagua drainage on the south and that of the westward flowing Río de la Pasión on the north extend the Alta and Baja Verapaz districts; these comprise an easterly extending spur of the main Sierra Madre. Where these highlands fall into the lowlands of the Petén, interesting data should be obtainable. It is an area, apparently, purely Maya. The country heretofore has been extremely inaccessible; it still remains one in which travel is by mule and on foot only, but its capital, Cobán, may be reached by airplane in two hours as against a previous five days or more. This territory forms the true base of the peninsula of Yucatán. Mr. Dieseldorff, a resident coffee-planter, has published descriptions of fine pieces, all Maya.

Taking into consideration the present state of knowledge in the Maya area, I believe that the following program is best fitted to meet the changing requirements:

1. Cessation of work at Uaxactún is recommended, because the six seasons at this site have given us all the detailed information that can be profitably assimilated at this time; further effort to obtain the correlation of the time-element between the various Uaxactún groups can not have the significance that the correlation of Uaxactún itself with other sites have.
2. The cessation of the work at Uaxactún should be followed by a period devoted primarily to the study and publication of the material already obtained, and secondarily to the determination of which highland site would most richly repay intensive examination. The reconnaissance necessary to reach this determination will naturally result in an invaluable ceramic collection from many sites. One season's exploratory work in the Petén using the Institution's camp at Uaxactún as a base would also yield much valuable archaeological information.
3. Inauguration of an intensive archaeological project in the highlands of Guatemala, be this the exhaustive examination of a single site for several years or the less extensive examination of several sites devoting one year to each.

22.2.

ALFRED V. KIDDER
Guatemala Highlands

YB 31:100–101, 1932

Mr. and Mrs. Ricketson spent the winter in Guatemala, studying the collections from Uaxactún and writing a final report upon E-Group, which will be published in 1933. Opportunity was taken to examine various sites in the highlands and a reconnaissance trip was made to Cobán in the province of Alta Verapaz, with a view to possible future excavations in that region. The Cobán district is known to be rich archaeologically and it is the Ricketsons' belief that its position on the northern slope of the highlands, overlooking, so to speak, the Petén, makes it probable that Cobán material might throw light upon the cultural relationships formerly existing between these two centers of Maya culture.

On July 17 Mr. Ricketson represented the Carnegie Institution at a special meeting of the Society of Geography and History of Guatemala, called for the purpose of presenting to the Institution a testimonial in appreciation of its scientific researches in Guatemala. Sr. Carlos A. Villacorta, the distinguished archaeologist and president of the Society, delivered the address of transmittal.

During the winter of 1932 advantage was taken of the temporary residence in Guatemala of Dr. S. K. Lothrop to enlist his aid in carrying out a preliminary examination of the archaeological remains on Lake Atitlán in the central highlands. Dr. Lothrop most generously donated both his services and a large share of the expenses of the work.

Attempt was first made to conduct excavations at Chuitinamit, the traditional seat of the Tzutujil rulers, a site of much importance because it is one of the few ruins in Guatemala where archaeology joins hands with written history. Opposition by the Indians of Santiago Atitlán forced cessation of work after a few trenches had been dug. The large collection of potsherds made by Dr. Lothrop will, however, provide material for a preliminary study of Chuitinamit.

Attention was next given to a survey of the south shore of Lake Atitlán. The entire lake front at the base of the volcano Toliman proved to be a single continuous archaeological site. Dr. Lothrop chose for investigation a locality known as Chukumuk on the summit of a ridge about 2.5 miles [4 km] from the town of Santiago Atitlán. He sank 22 test trenches which revealed debris of occupation to a depth of 8 feet [2.5 m], together with flexed burials accompanied by mortu-

ary pottery; and a group of eight decapitated individuals in the same grave, together with 22 pots and other artifacts.

The ceramic material comprises nine recognizable wares, whose stratigraphic and typological study indicates, in Lothrop's opinion, that the lowest Chukumuk finds have connection with early archaeological horizons of the valley of Mexico and of the Petén; as well as to the "Q" culture of eastern Salvador and the Chibcha culture of southern Central America. Intermediate Chukumuk pottery he considers to show relationship to later Petén and Copán wares, to Chorotegan incised and effigy types, and to Maya wares of Salvador and the Uloa [Ulúa] Valley. The latest Chukumuk is of much more local significance. It links with that of Chuitinamit, Utatlán and other protohistoric and historic ruins. It is obvious that the Guatemala highlands hold the key to many of the most important archaeological problems, not only of the Maya field, but of all Middle America.

In addition to the excavations at Chukumuk, examination was made of numerous house sites along the lake shores below Toliman of a type not previously encountered. Each house measured some 40 by 60 feet [12.2 m by 18.3 m] and had walls of dry stonework 4 to 6 feet [1.2–1.8 m] thick. The interiors were divided into four to six rooms, some walls still standing 4 to 6 feet [1.2–1.8 m] high.

Dr. Lothrop's forthcoming publication upon the work of the past winter will treat of the excavations and will contain notes upon other sites visited, both on Lake Atitlán and in the interior basins.

22.3.

ALFRED V. KIDDER AND
OLIVER G. RICKETSON
Minor Excavations in Guatemala

YB 34:120–123, 1935

A check-up of our present knowledge of Maya prehistory, undertaken during consideration of the ten-year plan mentioned in the introduction to this report, re-emphasizes the obvious fact that many parts of the area are archaeologically almost unknown. It has also become clear that while reasonably satisfactory

progress has been made in study of the Maya culture in its full flower during the Old and New Empires, very little light has yet been thrown on the outstandingly important problems of Maya origins and of the cultural and chronological relations between the developed Maya and other advanced groups in Middle America. Work, for example, is urgently needed in the southwestern part of the Yucatán peninsula and along the coastal plain of southern Veracruz, regions which should yield information upon early movements into northern Yucatán, as well as upon the source and nature of the later wave or waves of Nahuatl influence. The country lying between the Puuc and the Petén is studded with sites which should answer many at present extremely vexed questions regarding the cultural and time connections of the Old and New Empires. British Honduras, too, while its ruins are not spectacular, has been proved by Thompson to contain much material traded from other parts of the area. Investigation there should therefore provide valuable evidence for integrating our knowledge of Maya archaeology, particularly as regards ceramic developments. And the significance of the Guatemala highlands can hardly be overestimated, for in the mountain valleys should be found the remains of the early groups whose culture, according to the hypothesis held by in authorities, either through movement of people or by diffusion, fathered that of the Maya. The highlands, furthermore, seem always to have been the corridor for Middle American migration and trade. Highland sites, as is indicated by Lothrop's recent studies, show influences from both north and south, as well as from the Old Empire region.

A vast deal of almost virgin territory thus remains to be investigated. To work it at all thoroughly would require a very long time and much greater resources in funds and personnel than are available. Yet we should as quickly as possible obtain some idea of its archaeology in order that, within the 10 year period we have assigned ourselves for arriving at the stage of synthesis, we may envisage the major trends of Maya development. Even when no arbitrary time-limit is imposed, the soundest method of attacking any large archaeological field is to make an extensive preliminary sampling, for the purpose of locating strategic sites for intensive research. For this reason it is evident that major excavations at large sites should, for the time-being, be discontinued and our efforts be devoted to what may be called reconnaissance digging. The value of this sort of work has already been demonstrated by Messrs. Roberts' and Pollock's ceramic-architectural survey of northern Yucatán [Chapters 2.1, 2.2, 4.1, 4.2, and 4.3]. During the past season a similar campaign was inaugurated in Guatemala by reconnaissance investigations at Finca Miraflores in the highlands and at

San Agustín Acasaguastlán and Salama in the Motagua drainage.

FINCA MIRAFLORES

The great Miraflores-Arevalo mound group near Guatemala City has bulked large in the somewhat speculative writings upon the "Archaic" period and upon the genesis of Maya culture. Its clay figurines and pottery have been compared to those from the Valley of Mexico, from Salvador, from the Ulúa Valley, and from the early deposits at Uaxactún. But aside from excavations by Dr. Gamio in 1925, which were stated to have revealed stratified deposits, no "dirt-archaeology" had been done, nor does there exist any adequate description of the local ceramics.

The site, which lies in the outskirts of Guatemala City, consists of a large aggregation of earthen tumuli, most of which were apparently substructures for now vanished buildings of perishable materials. The work of 1935 was confined to test-pitting and trenching in search of refuse accumulations in which it was hoped that materials might be found, so stratified as to provide information regarding the nature and the sequence of the several ceramic periods which, according to Gamio, are represented at Miraflores. Best results accrued from the banks of a gully recently opened by seismic action. At that point rubbish extended to a depth of 3 m. Careful testing failed to reveal stratification, the material all seeming to emanate from a single culture horizon. However, a very large collection, of potsherds was made, as well as an apparently representative series of figurines. This material is of the sort which, rightly or wrongly, has been assigned to an early period. It will be studied during the coming winter. When published, it should give us a valuable datum for further typological research upon highland developments.

SAN AGUSTIN ACASAGUASTLÁN AND SALAMA

Maya culture is at present generally supposed to have been derived from the highlands and to have blossomed in the Petén. If this be so, one must postulate its relatively slow descent into the lowlands, for it is certain that those densely jungled regions could not quickly have been conquered for agriculture. It is therefore to be expected that chronologically and culturally intermediate remains should exist in the territory between the highland and lowland centers; and the country most likely to harbor them should be the upper and middle drainages of the great rivers that head in the mountains and skirt the Petén. An archaeological survey of the Motagua and Río Negro valleys was accordingly begun during the winter of 1935.

The site first investigated lies near the town of San Agustín Acasaguastlán, in the arid Middle Motagua. It is a long and straggling series of rock mounds skirting the Río Lato, a small northern tributary of the Motagua, which enters the latter just below El Rancho. The constructions proved to be of two sorts: substructure and burial mounds. No traces of early occupation were found, but interesting data were gathered regarding the vaulted tombs contained in the burial mounds. These were small subterranean masonry chambers, roofed with a corbelling of stone slabs, and covered with heaps of rock varying from one to 4 or 5 m high. Two chambers were opened and a number of others, previously cleared by the Guatemala government, were studied. There accrued a small collection of mortuary pottery. The most profitable part of the work, however, was the excavation of two rubbish deposits which yielded a great harvest of potsherds representing the wares in common use at the site. A report on the San Agustín burial chambers has been published (Kidder 1935).

It may here parenthetically be stated that the study of Maya ceramics has to date been sadly handicapped by the fact that practically all conclusions have had to be based on a very few fine vessels from tombs, many of which are most probably trade pieces and practically none of which are representative of the ordinary, everyday run of vessels serving the mass of the population. It is about as though a botanist were forced to draw inferences as to the flora of Long Island from the contents of the greenhouses on its country estates. However, such material as was gathered at San Agustín and Salama, and as is being collected at Chichén Itzá and in the Puuc, at Uaxactún and Copán, as well as that coming to light in the excavations of the University of Pennsylvania Museum at Piedras Negras, is rapidly supplying a large body of more reliable data for research upon Maya pottery.

The mounds at Salama, some 25 miles [40.2 km] northwest of San Agustín, are in the drainage of the Río Negro, which in turn flows into the Usumacinta. They are large earth tumuli, apparently not containing chambers like those of San Agustín. In the short time available it was not possible to make extensive excavations in the mounds, but trenching in their vicinity produced the usual large collection of potsherds.

The work at Miraflores, San Agustín and Salama proved, if nothing else, that even the most modest excavations result in a grist of ceramic material so extensive that months are required to work it up and prepare it for publication. When methods of handling such accumulations have been improved and standardized, when types have been established, and a start has been made toward building up a well-illustrated descriptive literature.

22.4.

ALFRED V. KIDDER

Guatemala

YB 38:243, 1939

Dr. Kidder spent the winter in Guatemala. Having finished, in 1938, the study of the nonpottery artifacts from Uaxactún and of the specimens from the Kaminaljuyú tombs, he was free to visit certain parts of Guatemala and Salvador which will sooner or later have to be investigated by the Division. A number of reconnaissance trips were accordingly made. At San Marcos in western Guatemala the collection recently made at Tajumulco by Miss Dutton of the School of American Research was studied; private collections in Quezaltenango were seen. Dr. Kidder also visited the ruins of Zaculeu, near Huehuetenango, and large mound sites at Aguacatán and Sacapulas. He spent a few days with Dr. Mary Butler of the University of Pennsylvania Museum, at her excavations in the very important Alta Verapaz district; and, after a trip to Copán, devoted 10 days to a journey through the Republic of Salvador. That country literally teems with antiquities: sites are everywhere, and both in the capital and in the provinces are large, and in some cases well documented collections, the careful study of which would go far toward formulating for later attack by excavation certain very significant problems regarding the eastern extension of Maya culture and the relations between the Maya and the peoples of Salvador, Nicaragua, and Honduras.

22.5.

A. LEDYARD SMITH AND

EDWIN M. SHOOK

Investigations in Guatemala

YB 39:269–270, 1940

Since the close of the Institution's excavations at the ruins of Uaxactún, in the department of Petén, the site has been made a center for the collection of chicle and a landing field has been established for its shipment to the coast by air. Taking advantage of its new acces-

sibility, Mr. Smith and Mr. Shook flew to Uaxactún in January and devoted a week to minor excavations and observations needed to supplement the data gathered during the original study of the ruins. The digging was for the most part in search of potsherds which would serve to place in their proper chronological position various deposits, buildings, and parts of buildings whose periods had not previously been determined with certainty, but which, during the writing of the final report upon Uaxactún, had been found to be of special significance. In this way the elaborate Structure E-VII sub and Temple B-XIII were assigned to the Chicanel and Tzakol phases respectively. Observations were also made on the ballcourt, and upon several stelae.

After Mr. Shook left to join Dr. Pollock in Yucatán, Mr. Smith proceeded to San Agustín Acasaguastlán, in the valley of the Motagua River, to conduct excavations and to explore the hitherto little-known remains in that region.

In 1935, a brief visit to San Agustín by Drs. Kidder and Ricketson had indicated that there were many tombs at the site and that the local culture differed in various ways from that of other Maya centers. Assisted by Dr. Gustavo Espinoza, Mr. Smith spent two months at San Agustín. His original plan called for two weeks of excavation, and six of exploration. The mounds investigated proved, however, so interesting and so rich in archaeologically valuable specimens that the greater part of the season was devoted to them. During this time a ten-room structure, which had perhaps been vaulted, was cleared; a ballcourt and a small temple were studied; and numerous pits and trenches were dug for the recovery of potsherds. The most important finds were made in a mound which held two tombs. These were of the slab-vaulted type known to exist at San Agustín but not previously examined by competent archaeologists. The vaults were rectangular chambers in each of which led an entrance passage sealed with large stone slabs. They appeared to have been kept in use for mortuary purposes for a considerable time, as each of the two held remains of many individuals, the bones of the earlier interments having been disarranged and pushed aside for later burials. From the vaults were taken a large number, of pottery vessels of various types, some of them of a beautiful Red, Black, and Yellow on Cream Polychrome Ware which has not hitherto been reported.

Preliminary study of the vessels from the tombs and the sherds from the general digging indicates that at least two ceramic periods are represented at San Agustín: one approximately contemporaneous with, but easily distinguishable from, the early Old Empire Tzakol phase of Uaxactún; the other somewhat later than the terminal Tepeu phase of the latter site.

Plumbate Ware, so far not found at Uaxactún, and believed, to date from the very end of the Old Empire, was in use during the time represented by at least the latest of the tomb burials.

Among the sherds are specimens which seem surely to be of nonlocal manufacture. Some of these are of wares characteristic of the Petén, others of Copán, and still others of the Guatemalan highlands. Owing, however, to the considerable time during which the tombs were in use, and to the extraordinary amount of building and rebuilding that took place at San Agustín, there seems to be a certain amount of mixing of materials of different periods. For this reason the sherd collections now at hand are not of maximum usefulness for determining the exact chronological relations of the two postulated San Agustín periods with the ceramic phases of other culture areas in the Maya field. It is nevertheless probable that further excavation specially directed toward that end would result in location of undisturbed and therefore pure deposits.

At the close of his excavations, Mr. Smith explored and mapped the Motagua valley and the lower courses of its tributaries for a distance of about 50 km from Zacapa to Progreso, finding many ancient sites in which were noted no less than 16,000 mounds of characteristic San Agustín type. Most of these are undisturbed. He also found ruins at a greater altitude near El Rancho which seem to represent a different culture. Their structures bear analogies to those of Rabinal.

22.6.

ALFRED V. KIDDER, R. E. SMITH,
AND A. LEDYARD SMITH
Guatemala

YB 40:297–298, 1941

The Guatemala City office, administered by Mr. R. E. Smith, continued to serve as headquarters for the Division's activities in Central America and for those of field workers from other institutions. To the latter it is often possible to be of assistance in supplying information regarding the country and as to customs and immigration regulations, in obtaining permits and contacts with government officials, and in providing

storage and laboratory facilities. The office is also often called upon to give help to travelers who wish to visit regions off the regular tourist routes.

Mr. R. E. Smith returned to Guatemala in January, where he and Mr. A. L. Smith have continued work on their print report on the excavations at Uaxactún. Mr. Tejeda, staff artist, spent two weeks at Copán, making paintings of the finer pottery vessels recovered by Mr. Strömsvik during recent years. He made other paintings of vessels in private collections in Salvador. At the office he drew and painted pottery excavated by Mr. A. L. Smith at San Agustín Acasaguastlán in 1940, and by Dr. Mary Butler, working under a grant from the American Philosophical Society, in Alta Verapaz. It is impossible to exaggerate the beauty and the meticulous accuracy of Mr. Tejeda's reproductions of material of this sort.

By courtesy of Governor W. Cameron Forbes, Chairman of the Institution's Board of Trustees, Dr. Kidder was able to accompany him on a trip to the Bay Islands, off the north coast of Honduras. Information was obtained as to prehistoric sites on the islands which it is hoped may eventually be investigated by the Division. Governor Forbes and Dr. Kidder later flew to Copán, to inspect the work of Mr. Strömsvik. Dr. Kidder, after visits to Mr. Dimick's excavations at Campana San Andrés in Salvador, and to those of Mr. Richardson in Nicaragua, spent two weeks on a study of the great archaeological site of Kaminaljuyú in the outskirts of Guatemala City.

Kaminaljuyú had been mapped by Mr. T. R. Johnson and Mr. E. M. Shook in former years, and excavations, had been made in certain parts of the site, but a thorough surface examination of its 200 or more mounds had not previously been undertaken. It revealed much of interest regarding the grouping of the mounds. In particular, there were noted at least, eight long, narrow constructions, whose parallel sides suggested that they might be ballcourts, but which lacked the open or expanded ends characteristic of all such courts which had hitherto been noted. To ascertain their nature, Mr. A. L. Smith ran a series of test trenches in one of them, finding a pair of tenoned stone parrot heads on opposite sides at the middle and evidence that there were sloping benches on either side of a playing alley. The latter indications, together with the fact that tenoned serpent or parrot heads have been found in similar positions in ballcourts at Copán, San Agustín Acasaguastlán, and San Pedro Pinula, renders it certain that most, if not all, of the Kaminaljuyú structures served that purpose. One or more of them will be more fully examined in the near future.

22.7.

J. ERIC S. THOMPSON
Guatemala: Pacific Coast

YB 41:267–269, 1942

The considerable number of fine sculptures in the neighborhood of Santa Lucía Cotzumalhuapa, Escuintla, on the Pacific slope of the Guatemalan highlands, are of prime importance in determining the history of Mexican-Maya relations. The style, subject matter, and hieroglyphs; of the monuments have long been recognized as of a distinctly Mexican cast, but the chronological position of Mexican enclave has been a matter of much speculation. The ruins have usually been attributed to the Pipil, a Nahuatl-speaking group, a part of which was settled in eastern Escuintla at the time of the conquest, but the question of when these sites flourished could not be solved without excavation.

At the end of January 1942, Mr. Ralph L. Roys, Mr. Thompson, and his photographer, Mr. William Webb, made a tour of the central and western parts of the Pacific coastal slope to decide on a place to excavate and to inspect sites and collections with a view to obtaining information on the general archaeological picture in this area. The most interesting outcome of this reconnaissance was the discovery of two stelae at a large site on the Fincas San Isidro Piedra Parada and Santa Margarita, near Acintal, in the southeast of the department of Quezaltenango. Both stelae were carved in the easily recognizable style of Izapa (Tuxtla Chico), a site in southeastern Chiapas. One of them, however, had an Initial Series introductory glyph followed by the number 7, expressed by means of a bar and two dots. There was a plain surface immediately below, indicating that the number had not been associated with a glyph, but the rest of the surface has flaked off. This stela, therefore, falls into the small and very perplexing group of monuments which have numbers but no glyphs, and which, in the opinion of some archaeologists, are of extreme antiquity. It is difficult to hazard whether the complex scrollwork of this Izapa type denotes the over-elaboration of a primitive style or the sophistication of a late rococo development. Near by was a boulder carved with a kneeling figure, perhaps a ball-game player, in the style commonly known as Olmec. The site is large, and because of the diversity of styles (there is also extremely crude sculpture there) and because Plumbate sherds indicate that its occupancy may have been extended, excavation there might be well repaid.

Following this preliminary reconnaissance, Mr. Thompson and Mr. Webb proceeded to El Baúl, a sugar

plantation near Santa Lucia Cotzumalhuapa, where through the courtesy of Mr. Carlos Herrera, one of the owners, and Mr. Julio García Salas, the manager, they were invited to stay as guests of the plantation as long as the excavations lasted. El Baul is of archaeological importance because among the sculptures found there is the Piedras Herrera, another of the group of stelae with numbers unattached to glyphs. This has been read as an Initial Series recording the very early date 7.19.7.8.12. It was desired to determine whether ceramic evidence bore out this early attribution, and it was also hoped to date the Cotzumalhuapan sculptural style, of which good examples also occur there, in terms of ceramics.

Considerable quantities of sherds were obtained, but, unfortunately, no clear-cut stratification. Two periods are, however, represented, and there are slight traces of a third. The latest, which includes Plumbate vessels of simple forms, but not those which found their way in trade to remote parts of Middle America, appears to be coeval with the Amatlé horizon at Kaminaljuyú. The earlier is close to the Esperanza horizon of Kaminaljuyú. There were also a very few sherds which stylistically belong to the still earlier Miraflores horizon. One pyramid was partially excavated, bringing to light a very fine low relief sculpture in Cotzumalhuapan style which represented the upper half of a deity or personage emerging from the body of rather realistic crab. This pyramid also yielded two heads of snakes in the round, a stone with the date 4 Quiauitl, the glyph being represented by a full face view of the head of Tlaloc, and a stairway of large, well dressed stone blocks. The pottery has not yet been studied in detail, but at least it can be said that among the very few sherds in the soil in front of and level with the butt of the Piedras Herrera are included some which are very probably of, the later horizon.

Pottery from Tiquisate, Suchitepéquez, is almost exactly the same as that of the later period at El Baúl, and other sites on the Pacific coastal slope have several ceramic types in common with El Baúl. At the site of El Castillo, about 1.5 km from El Baúl, the presence of round monolithic columns was noticed. Some of these were in the soil at the foot of a mound, others had been set up around the hacienda building. Visits were paid to the neighboring fincas of Pantaleon, Los Tarros, Aguna, and Xata, where archaeological material was inspected. The many examples of sculpture at Pantaleon are well known, but it is not generally realized that some of these pieces came from El Baúl and neighboring fincas.

Mr. Thompson spent the month of April in Guatemala City making notes on the sherd material from El Baúl in order to avoid the necessity of shipping the collection. One interesting point has developed,

namely, that the sherds of Plumbate Ware, many of them poorly fired, it would seem, are of forms such as shallow bowls and simple cylindrical vases. None are of the more elaborate effigy vessels or composite silhouette jars which are so widely distributed. Since Mr. Kidder found a similar situation in the Amatlé horizon at Kaminaljuyú, and in view of the associated pottery at both sites, it seems not improbable that these simple forms of Plumbate are anterior to the development of export to distant markets.

During a brief reconnaissance in the highlands, in company with Mr. Roys, two important groups of ruins near Sacapulas were visited. One, Río Blanco, on the peninsula formed by the confluence of the Blanco and Negro rivers, was found to have an oval pyramid and a ballcourt in a good state of preservation. The second, Chutixtiox, situated on a steep hill to the north of the Santa Cruz Quiché road and about 4.5 km from Sacapulas, has some remarkably well preserved buildings, including a *monoztli* (a small pyramid-like platform) with the plaster still in position on most of the almost perfect surface, and a room about 24 in. long, the back wall of which was standing to a height of about 2.7 m.

22.8.

A. LEDYARD SMITH

Guatemala Highlands Project

YB 44:166–168, 1945

During the winter of 1944–45, Mr. A. L. Smith, assisted by Sr. César Tejeda, spent four months in archaeological reconnaissance in the departments of Huehuetenango and El Quiché. The purpose of the work was to obtain as much information as possible, without intensive excavation, as to both hilltop and valley sites with a view to selecting representative examples of each type for future excavation. All sites were mapped, architectural details were recorded by drawings and photographs, and samples of pottery were recovered from inside or below constructions as well as from the surface. Special effort was made to locate refuse dumps.

The trip was made in the Institution's station wagon, and local labor was employed. The hiring of workmen was greatly facilitated by the cooperation of the Minister of Public Education, the governors of de-

partments, and the mayors of the towns and villages visited. Seventeen sites were examined, some large and some small, all within fairly easy access of a main highway.

Huehuetenango, capital of the Department of Huehuetenango, was the first base used. In this region seven sites were investigated: Zaculeu, Cambote, Chicol, Piol, Xetenan, Cucal, and Pucal. Of these, Zaculeu, a fortified site surrounded by barrancas on three sides, proved to be by far the largest and most interesting. It lies about 4 km northeast of Huehuetenango. Considerable excavation has been carried on here in the past, the Guatemalan government in 1927 having excavated and partially restored the principal mound, a large pyramid surmounted by a temple. About 10 days were spent at Zaculeu in recording materials for restored drawings of several buildings and a ballcourt. A large collection of potsherds was also made. Cambote, directly south of Zaculeu and in plain view there from, rests on a tongue of land; but is not so well protected as Zaculeu. Very little masonry was showing here, and there was no ballcourt. Chicol, Piol, and Xetenan are all small hilltop sites practically surrounded by barrancas. All three have ballcourts. Cucal is a small valley site without a ballcourt. At Pucal, a small hilltop site near Cucal, only one mound remains, but there is evidence that there were several others which had been leveled for agricultural purposes, the stones being used in the building of modern fences.

The next base of operations was the village of Aguacatán, about 26 km east of Huehuetenango in the Department of Huehuetenango, where a month was spent investigating Huitchun, Chalchitan, Xultún, and Chichoche. Huitchun, sometimes called Chichun, rests on a low hill just west of the village. It is a small group surrounding a court and has a ballcourt. Chalchitan, one of the largest sites visited, and the one to which most of the month's work was devoted, lies in the valley just east of the village. Unfortunately a great many of the mounds had been dug into by treasure hunters, causing much damage to inner constructions. There is still much left, however. One of the two ballcourts was excavated and found to cover an earlier ballcourt, within which there was evidence of still earlier construction. Two nicely carved stone heads, one of a serpent and the other of a jaguar, were recovered from high up in the center of the playing walls of the earlier ballcourt. A tomb with a corbelled vault was discovered in one of the largest mounds. This had been looted years ago. Probably the most interesting find was a building showing six distinct architectural phases, the most instructive of which were a platform with four round columns, one off each corner, and a later construction of four walls with stepped tops. There

is much pottery of all periods at Chalchitan. Xolchun, east of Chalchitan, is a good-sized hilltop site. Its main features are a well preserved ballcourt, terracing, block masonry, and a type of late pottery with white geometric design on a red slip. Chichoche is a small group of mounds in sight of Xolchun across the barranca to the southeast.

Sacapulas, a village in the Department of El Quiché about 37 km east of Aguacatán, was the last place used as a base. From here the ruins of Chutixtiox, Chutinamit, Pacot, Xolchun, Río Blanco, and Xecataloj were studied. The best preserved of these is Chutixtiox, a hilltop site extremely well protected against attack, its only entrance being blocked by a wall. The main group is on a high terrace with stairways on all sides. An interesting feature is a stucco jaguar in a crouching position at the base of one of the several platforms. It was possible to take measurements of almost all the buildings. Chutixtiox is similar to Xolchun in that it has the same kind of ballcourt, a great deal of terracing, and the same White on Red pottery. Chutinamit, just outside Sacapulas, is another well protected hilltop site, almost completely surrounded by barrancas. Its only entrance, on a narrow neck of land to the north, was protected by three parallel walls stretching from barranca to barranca. Pacot, also almost inaccessible, is small, but the buildings are well preserved. Xolchun, not to be confused with the Xolchun in the Department of Huehuetenango, lies on the tongue of land formed by the junction of the Río Blanco and the Río Negro. A stela, used as the capstone of a tomb, was found in a small temple. Its upper part bore a well carved geometric design. A most unusual structure was an oval, almost circular, platform with seven terraces. Río Blanco, a small valley site, shows several periods of construction, and the types of pottery found there indicate along occupancy. Among the wares noted were Plumbate and Utatlán. Xecataloj is a small valley group on the north bank of the Río Negro about 1.5 km east of Sacapulas.

It would appear that the well protected hilltop sites are later than the more vulnerable valley sites. Before definite conclusions are reached, however, the collections of potsherds, now in the Institution's office in Guatemala City, must be studied. Probably of significance is the fact that the White on Red Ware occurs only at hilltop sites. Another point is the fact that those in the valleys all have several architectural periods, whereas in most cases the hilltop sites do not. The latter are characterized by much terracing, ballcourts with well marked end zones, and split stairways with balustrades. The mounds are usually grouped about a plaza with one or more small platforms in the center. Ball courts in the valley sites lack end zones. At present the two groups that appear most desirable to excavate

are Chalchitan and Chutixtiox: Chalchitan because of its long occupation, its architectural and ceramic sequence, its accessibility, and the availability of good labor at Aguacatán; Chutixtiox because of the excellent preservation of buildings of various types and because it could conveniently be worked from a base at Sacapulas. Final choice, however, should be postponed until, further reconnaissance of the highland region has been carried out.

22.9.

A. LEDYARD SMITH

Guatemala Highland Project

YB 45:199–201, 1946

During the 1945–46 field season Mr. A. L. Smith, assisted by Sr. César Tejeda and Mr. Douglas Binney, continued the archaeological reconnaissance of the Departments of Huehuetenango and Quiché. Permission to operate was granted by the Minister of Public Education, Dr. Manuel Galich, whose effective cooperation, together with that of the Governor of Quiché and the mayors of the various villages visited, greatly facilitated the recruiting of labor. Fourteen sites were investigated and roughly mapped, and individual structures measured and photographed. In several instances circumstances seemed to warrant fairly extensive digging, which at one site revealed a building sequence and at each of two others resulted in discovery of rich tombs.

The first week was spent at Sacapulas working at the nearby fortified hilltop site of Chutixtiox, investigated and mapped last year. The ruins were thoroughly bushed and cleared for an aerial photograph, and Structure II was excavated in hopes of finding a tomb. None was found, but the structure, a small platform supporting the remains of a superstructure, proved to have been added to at least three times. Chutixtiox dates from the period of the Spanish conquest or very shortly before. Its buildings are in an excellent state of preservation and it lies close to the main highway between Sacapulas and Huehuetenango. A fence has been put up to protect it from cattle, and, to make it more readily accessible, the Governor of Quiché plans to build a road tip to it from the highway. It is without doubt one of the most strategically and picturesquely situated ruins in Guatemala.

During the second week, Quiché, the capital of the Department, was used as a base of operations. In this region three groups were investigated: Comitancillo, Sac Lac, and Laguna Seca. Comitancillo, a well fortified site, about 34 km north of Quiché, proved to be the most interesting. The ballcourt, the most important of its 13 structures, is in a very good state of preservation, has closed end zones, and still retains traces of red, blue, and yellow paint. Another structure of interest is a small truncated pyramid with stairways on three sides. This building apparently was originally completely painted red. Among the sherds recovered was a good percentage of White on Red Xolchun pottery, a ware found in many of the fortified conquest-period sites. Sac Lac is a small plaza group situated on a plain about 3 km southeast of Comitancillo. It is now used as a cemetery. Laguna Seca, another small plaza group, about 2 km west of the village of Joyabaj.

Nébaj the third largest town in the Department of Quiché, was chosen as the next base. The original plan was to spend about three weeks here, and then move on, but, the area proved to be of such interest that the rest of the field season, with the exception of a week at the Brol finca, was spent here. In the immediate vicinity, the ruins of Nébaj, Vitenam, and Tixchun were studied. The two latter are small, unimportant ball-court groups. The ruins of Nébaj, in the valley just southwest of the town, are quite extensive. The mounds are very large and surround several plazas and courts. In the main plaza there is an alignment of large rough stones whose arrangement may have had astronomical significance. Although one of the largest sites in the Department, Nébaj does not have a ballcourt. During its investigation a depression was discovered at the base of one of the principal mounds. The possibility that this might have been caused by the caving-in of a tomb made excavation seem worth while. After two weeks of digging, we finally encountered the tomb at a depth of over 9 m. It consisted of a square stone chamber roofed with a corbelled vault, entrance having been gained by means of a stone passageway 5 m long sealed with a single stone slab. The vault had collapsed, causing the depression above. Besides the human remains, over 40 pottery vessels and some 250 pieces of jade were recovered. The pottery is of the general period represented by that of the late Tzakol and early Tepeu phases at Uaxactún. Before the work was finished at Nébaj, all the stone monuments were whitewashed in readiness for aerial photographs, kindly taken by Colonel Arthur Binney, U. S. Naval Attaché in Guatemala, of the Nébaj mounds, Chutixtiox, and other ruins.

Still using Nébaj as a base, we visited and mapped several sites near the neighboring villages of Chajul and Cotzal: Huil, Oncap, Mutchil, El Tigre, Acitiz,

Pulai, and Vicaveval. Huil lies on the side of a hill about 10 km north of Chajul. It is a ball-court group consisting of a rectangular plaza with the ballcourt at one end and structures on the other three sides. A small platform, now used as a shrine by the Indians, stands in the center of the plaza. There are several stucco monuments here in the form of human figures. The ballcourt has no end zones and, like most of the Huil structures, is very well preserved. The ruins of Oncap are about 6 km southwest of Chajul. In plan it closely follows Huil, and it is in an equally good state of preservation. Mutchil and El Tigre are two small ball-court groups on Finca Santa Abelina, the property of the Hodgson family, some 10 km northeast of Cotzal. Both sites have open-end ballcourts. El Tigre was so named because a stucco jaguar was found in the ruins. Acihz and Pulai are two small ball-court groups lying in valleys, the former about 4 km south and the latter 7 km southwest of Cotzal. The courts have no end zones, and very little masonry appeared at either. The ruins of Vicaveval, a half-hour's walk northwest of Cotzal, are well protected in a depression near the top of a high hill. Its ballcourt, which has closed end zones, is situated in the center of the depression, three sides of which rise in terraces to a height of over 20 m and form a regular stadium from which to watch the game. On the opposite side of the hill from Vicaveval and a little higher there is a cave in which were the remains of at least 40 skeletons. Twenty-two skulls were still there, but many had been taken away over a period of some years. No pottery was found with the skeletons, which undoubtedly date from before the conquest. A good deal of burnt wood was scattered among the bones.

The season's work was wound up at the Brol family's Finca San Francisco, some 17 km northeast of Cotzal. There are two ruins: San Francisco and Tzicuay. The former, in a cane field on the edge of the Río Chipal 0.5 km southeast of the Brol residence, was mapped by Robert Burkitt some 33 years ago. Today there is practically no masonry showing. It is a ball-court group, the court having end zones. Tzicuay, also a ball-court group, is on the tip of a low promontory projecting from the side of a high range of hills, about 1.5 km west of the Brol residence. The buildings retain considerable masonry. The ballcourt has well marked end zones; in its east range is a masonry tomb with corbelled vault and short entrance passage. Unfortunately, it had recently been entered and disturbed, but 74 pottery vessels were recovered, most of them unbroken. Although it has as yet been only cursorily examined, the pottery appears to represent a long sequence of phases, from an early one, possibly contemporaneous with the Chicanel ceramic phase of Uaxactún, to a phase containing the relatively late Plumbate Ware. This and the fact that many skeletal remains were found pushed to

the sides of the tomb to make room for later burials indicate that it was in use for many generations.

It was originally planned to investigate the Rabinal area in the Department of Baja Verapaz, but the unexpectedly long time required for the excavation of Néabaj has forced postponement of that part of the reconnaissance until next year.

22.10.

EDWIN M. SHOOK

Guatemala Highlands

YB 46:179–184, 1947

Mr. Shook resigned from his position with the United States Government and returned to the Division in August 1946. Early in October he began preparation for field work in the southwestern highlands and on the Pacific coast of Guatemala. An intimate knowledge of most of this area and the contiguous region of Chiapas, Mexico, had been gained during three years' service on the government's Cinchona Procurement Program. As complete a record as possible, under the circumstances, had been made of the archaeological remains throughout the zone. The information thus gathered showed that the narrow strip of hot coastal plain from sea level to approximately 300 m elevation had witnessed the ebb and flow of pre-Columbian Indian culture from the earliest horizons known in Guatemala to the time of the Spanish conquest. Sites ranging from small clusters to great groups of mounds, each over a kilometer in extent, line the banks of the many streams crossing the fertile plain. The site of Itzapa, just across the Mexican border in Chiapas, is typical of the large ruins. With a few exceptions, the remains above the 300 m elevation on the Pacific slope of the cordillera are small and widely scattered. Tajumulco, is typical of these sites. Not until the broad inland valleys and plateaus north of the volcanic mountain range are reached does one encounter ruins, of considerable size. An examination of private archaeological collections and surface sherd samples from southwestern Guatemala showed Plumbate pottery to be most abundant down the Río Cusulchima and Naranjo valleys, fanning out over the Pacific slope and coastal plain from these drainage systems.

The first activity of the field season was a reconnaissance of the northern half of the San Marcos

Department and the Río Cuilco valley of southern Huehuetenango, not only to search for the source of Plumbate pottery, but to fill the remaining void in the archaeological picture of southwestern Guatemala. A suitable base of operations was established at the United States Government cinchona plantation, Finca El Porvenir, situated on the south slope of the Tajumulco volcano. The trip from El Porvenir, to San Marcos and Tejutla, was made by automobile on October 23. Thereafter, a ten-day circuit of 200 km was made on foot and horseback to Sipacapa, San Miguel Ixtahuacan, Antigua Tutiapa, Cuilco, Canibal, Tectitan, Tacana, Ixchiguan, back to Tejutla, and then by car to El Porvenir. Over 30 minor sites were recorded. Each of the modern towns mentioned, with the exception of Ixchiguan, had one or more archaeological ruins within the town or on the outskirts. The most important zone appears to be the Cuilco valley, where remains occur at short intervals on both sides of the river; others are situated in tributary valleys and on spurs of the Sierra Madre directly above the Río Cuilco. One well preserved hilltop site, Pueblo Viejo, 8 km southwest of Sipacapa, has exposed masonry of cut semi-block and slab stones laid in mud mortar. At Chilipe, 7 km south of Cuilco, a well defined open-end ballcourt was found, the only ballcourt seen on the trip. The previously known ruins of El Reparo, 10 km below the town of Cuilco, were visited and a large stone monument and urn burial discovered. The monument, carved in the round and depicting a full standing human figure, stood on the lowest step of the principal pyramid. The burial of a young adult was found below the top floor of the same pyramid in a large red ware urn with another pottery vessel inverted over the lower as a cover. Although surface sherds were examined and samples collected, no Plumbate Ware, was seen at any site visited on the trip. This is of particular significance in the continuing search for the manufacturing center of this most widely traded Mesoamerican pottery.

The second part of the field season consisted of a series of excavations on the Pacific coastal plain paralleling the Guatemala-Mexico frontier. El Sitio, the first site investigated, is an enormous group of mounds formally arranged around plazas with monuments of plain columnar basalt. The ruins lie along the east bank of the Río Gramal, a small tributary of the Río Suchiate, 18 km north of Ayutla, on the highway to Catarina and Malacatan. Five test pits were sunk: four through platforms and mounds from surface to sterile subsoil, the fifth on level ground at the north edge of the site away from ancient construction. This last test produced a mixed lot of material from two distinct occupations of El Sitio. The earlier belonged to the Middle Culture horizon contemporaneous with the

Miraflores phase in Kaminaljuyú, whereas the later occupation occurred during the Postclassic period, as Plumbate pottery was well represented. The burial of an important personage was found below the floor of a terrace or platform. A huge pottery urn covered by another inverted vessel contained the body, jade beads, and ornaments. Other burial furniture was on the outside, including a finely carved stone scepter. The major occupation and greatest architectural activity took place at El Sitio during the Late Middle Culture period.

A small site, La Libertad, on the east edge of the highway, 14 km north of Ayutla, was next investigated and proved to be contemporaneous with the late occupation at El Sitio. Plumbate sherds occurred in each level of the stratigraphic cut. Similar evidence was recovered at Santa Romelia, where a group of scattered mounds on both banks of the Río Seco, 10 km north of Ayutla, indicated a small village rather than a large ceremonial center like El Sitio. Again, Plumbate was evenly distributed from top to bottom of the test cut and amounted to 30 percent of all sherds. Here the results show that Plumbate pottery served a utilitarian as well as a ceremonial purpose.

At Ayutla single small groups of mounds may be found anywhere on the plain between the Suchiate and Melendres rivers. During the leveling for a railroad siding, about 75 cm of the ground surface was cut down and archaeological material equivalent to Santa Romelia and La Libertad was exposed. Just east of Ayutla on the west side of the Río Melendres another major site, El Jobo, comparable in size to El Sitio and Itzapa, was discovered. Pyramidal mounds up to 15 m in height and a multitude of lesser structures, arranged in an orderly manner around plazas, extend approximately 1 km along the riverbank. A finely carved stela of the Itzapa style, and two urn burials accompanied by some 40 pottery vessels were found in El Jobo. The burials and furniture belong to the Middle Culture horizon and are contemporaneous with the early occupation of El Sitio. Unfortunately the stela had been disturbed and broken in recent times and lay at the foot of a mound. An unsuccessful attempt was made to locate its base and associate the stela with the ceramic material. The structure with which the monument was associated had been built during the early period, but surface sherds of Plumbate also indicated that El Jobo had a more recent occupation. A small site, Buena Vista, just south of El Jobo and possibly an outlying group of that large center, produced from the central fill of a mound a large Plumbate burial urn containing the skeletal remains of a child, and a beautiful jar of the same ware.

There are many archaeological ruins on the fertile strip of land from Ayutla to Ocos between the Río

Suchiate and the Naranjo. The major sites are Santa Clara, Los Limones, and La Zarca, 6, 10, and 13 km respectively below Ayutla. Another Plumbate burial urn containing an infant skeleton was found in a mound at Santa Clara, and a ballcourt of the open-end type was discovered.

On the Hacienda Los Limones there are two sites: one on the east bank of the Suchiate, the other on the west side of the Naranjo. The latter has a type of construction hitherto unknown on the Pacific coastal plain. The substructures consist of a hearting of sandy brown earth encased by masonry terrace walls of small, selected river-worn stones laid in lime mortar and finished with a heavy layer of excellent lime plaster. The lime was derived from sea shells; in many instances the unsuccessfully burned shells or their fragments appear in the mortar. Unfortunately the short stay at Limones produced no pottery to aid in the placement of this site in the cultural sequence.

La Zarca is a major site located on the east bank of the Suchiate. No excavations were undertaken, but a ceramic sample was obtained from the local farmers, who are constantly unearthing archaeological specimens during crop planting. The material showed that La Zarca had the same occupational range as El Sitio and what appears to be a post-Plumbate period. Characteristic of this phase are Red on Cream Ware tripod bowls with tall, bird head-effigy feet. Some of these bowls have striations on the interior similar to grater bowls or *malcajetes* from late horizons in the Valley of Mexico.

The small, briefly investigated site of La Victoria, 17 km south of Ayutla and 3 km inland from the ocean, produced a relatively high percentage of solid, hand-modeled figurines of the so-called Archaic type, now assigned to the Middle Cultures. Again the presence of Plumbate in the surface levels indicated a more recent occupation.

The third part of the field season, from late January to early March, was spent on Finca El Paraiso, a coffee farm on the Pacific slope at 1,000 m elevation. El Paraiso is located in the Chuva zone of the Department of Quezaltenango, 10 km by road north of Colomba. The owners, Srs. Vitalino and Benjamin Robles, during the course of coffee cultivation, have made important archaeological discoveries over a period of many years. The majority of the objects they found came from an insignificant-looking low mound on a level bench of land jutting out from the main mountain range. Undoubtedly, the mound was the principal structure of a small village occupied during Late Classic and Postclassic times. In the upper part of the mound the Robles found two gold disks associated with effigy Plumbate pottery; in 1943, assisted by Sr. César Tejada, they encountered a cache of many ves-

sels without metal at a greater depth. The specimens were made available to the Division for study, and a generous invitation was extended by the Robles to make further investigations in El Paraiso. Accordingly, Dr. Kidder and Mr. Shook planned to devote from three to six days there, thoroughly recording all data. It actually required six weeks, so rewarding were the excavations.

A north-south trench was dug through the mound's center, disclosing its construction. It was an earth and stone-filled platform with vertical exterior walls heavily backed with water worn boulders. The platform probably once supported a structure of perishable material. Within the platform was found a red-painted, stone-lined, richly stocked tomb sunk through subsoil prior to the platform's construction. It contained the skeleton of an adult seated cross-legged on the floor, backed against the north wall, facing south. Another human skeleton lay diagonally across the floor of the tomb. Around the dead, covering the available floor space, had been placed a wealth of furnishings; the tomb was then filled, and other offerings were piled in a heap above the closed tomb. This was the pottery cache discovered by the Robles in 1943. The tomb and cache contents included jade and shell beads and ornaments, obsidian lancets, an iron-pyrite mosaic mirror, nine pottery bells, three drums, one flageolet, one whistle, three figurines, nine spindle whorls, and over 67 vessels. Plumbate was the most abundant ware found in this tomb.

Near the platform's center, 3.5 m below the surface, another interment had been made before construction of the mound. Two large pottery urns, each containing an adult body, were found side by side, each covered by an inverted vessel. The furnishings, both inside and outside the urns, included jade beads and ornaments, small black polished pebbles, an iron-pyrite incrustated mirror, pottery spindle whorls, and vessels. Several of the latter are of Plumbate Ware. Many caches of one or more pots were found throughout the fill of the mound, some having been put there during construction, others near the surface having possibly been buried after completion of the mound. We believe that the two thin gold disks and effigy Plumbate vessels discovered by the Robles belong to the later of these caches.

West of the platform the land slopes sharply to a ravine called La Gruta, from the head of which issues a spring of cool, crystal-clear water. Carvings on natural rock outcrops and the abundance of potsherds led the Robles to investigate. They uncovered a line of flagstones and a rich deposit of sherds, and had the fortitude to resist further digging until our arrival. The flagstones proved to be those of a broad paved terrace facing the spring. A stone stairway descended to the terrace from the direction of the village site above. At a right

angle to the natural slope of the ravine's north side, an underground passage, large enough to permit a short man to walk erect, led 7 m into the hillside from the paved terrace. At that distance a stairway ascended to the interior of a circular structure somewhat resembling a Southwestern Pueblo kiva. It consisted of a central fire pit encircled by two flagstone benches, one above and set back from the lower, like seats of an amphitheater. The maximum inner diameter of the top bench was 5.65 m. The level of this bench averaged 1 m below the soil surface prior to the 1902 eruption of Santa Maria volcano, which added about 1 m of pumiceous ash to the Paraiso region. The fire pit of the circular structure was filled with broken metates and unworked boulders, all severely burned. The passage served as a drain as well as an entrance, as far as the terrace below, where a well made, stone lined, slab-covered drain channeled the flow of water along one side of the terrace to the ravine. No conclusive evidence was obtained on the use of the circular structure or on the method of roofing. It is believed to have been roofed and possibly to have served as a ceremonial or communal sweat bath. The ceramic material from La Gruta proved the contemporaneity of the circular structure and the village site at El Paraiso.

The fourth part of the field season, from mid-April through May, was spent in exploration and excavation on the lower coastal plain south of Tiquisate in the Department of Escuintla. Recently the United Fruit Company began clearing this area for new banana plantations, digging deep drainage canals and building roads, in the course of which work a wealth of archaeological material was exposed. Through the kindness of the Company officials and particularly the Tiquisate manager, Mr. A. L. Bump, the opportunity was offered the Division to investigate the area. Excavations were made on Ticanlu, Tacana, Zunil, and Toliman farms, and surface sherds collected at Las Trozas, Huisisil, Ixtepeque, and Pacaya. Many of the ruins bordered on a dry stream bed between the present Nahualate and Naranjo rivers. If the stream dried up or radically shifted its course during the occupation of these sites, it must have had a profound effect on the inhabitants. The excavations in four of the ancient settlements along the dry stream bed proved that they flourished vigorously during the Early and Late Classic periods. Then activities abruptly ended and the area, at least that part investigated, was abandoned. No effigy or Tojil period Plumbate or post-Plumbate material was recovered in the excavations or was seen in any of the private collections in Tiquisate. Prior to the Early Classic surge in Tiquisate, apparently a thinly scattered population inhabited the zone, as a small amount of Middle Culture material was found. Diagnostics of this period are solid, hand-modeled figu-

rines and certain forms of Usulután Ware pottery. During the field season, visits were made to Copán and Zaculeu to keep abreast with the work of others. Dr. Kidder and Mr. Shook briefly inspected the ruins of San Cristóbal, Department of Totonicapán, and Piedra Parada, Santa Isabel, Canchón, and Virginia, Department of Guatemala. They also began the recording of the immense Robles Collection of pottery and artifacts in Quezaltenango. Mr. Shook continued compiling information on modern sweat baths and on the manufacture or archaeological counterfeits in Guatemala.

22.11.

A. LEDYARD SMITH

Guatemala Highlands

YB 46:184-187, 1947

The work carried on during the 1946-47 field season consisted of the following activities: reconnaissance in the Departments of Baja Verapaz and Quiché; excavations at Nébj, Department of Quiché; visiting various sites in the Departments of Huehuetenango, Baja Verapaz, and Quiché in order to gather material for reconstruction drawings.

During the first five weeks of the season's work, Mr. A. L. Smith, assisted by Sr. César Tejeda, carried on archaeological reconnaissance in Baja Verapaz. Six sites were visited: Cahyup, Chuitinamit, Pichec, Toloxcoc, Pachalum, and El Portón. Plans of these sites were made, individual buildings measured and photographed, architectural details recorded, and, where possible, surface collections of pottery recovered. The two most interesting ruins were Cahyup and Chuitinamit in the Rabinal area. Both of these are fortified sites of the conquest period situated on the crests of high hills on the north side of the valley of Rabinal, the former at its east end, the latter northwest about 8 km down the valley. At the time of the conquest the Spaniards attempted to conquer the valley of Rabinal, but were driven out, and it was not until after the Indian rulers at Cahyup and Chuitinamit were converted to Christianity by Las Casas and Father Angulo that the Spaniards finally occupied the valley.

The ruins of Cahyup lie about 2 km, north of the village, of Rabinal. There are five groups. The main group crowns the top of a hill some 250 m above the valley. The 22 structures that form this group are lo-

cated in and around three plazas and consist of temples placed on high platforms, long single-room buildings with multiple doorways, and altar platforms. The single-room buildings form two or three sides of a plaza and face upon it; temple structures are placed in the plaza and are associated with one or more altar platforms. One of the most interesting structures at Cahyup is a large pyramid supporting two temples, each resting on its own platform. Two other groups are on hills to the north and northeast of the main group; the remaining two groups lie in the depression between the hills. Irregularly placed on the slopes leading down into the depression mentioned above are short terraces which undoubtedly once supported houses of perishable materials. A most unusual construction was found on a high hill about 1.5 km north of the main group. This proved to be a solid, round masonry structure 2.4 m high with five terraces rising to a flat top. It may have been used as a watch tower or signal post.

The ruins of Chuitinamit consist of eight groups extending along the top of a ridge about 300 m above the valley. The general direction of the ridge is northeast and southwest. The groups are well separated so as to form definite units. With the exception of two ballcourts, a type of construction not found at Cahyup, the two sites have similar structures arranged in much the same way. The ballcourts are of typical conquest site design, with end zones enclosed by high walls and stairways leading out at either end. One of the courts had never been completed. Southwest of the most northeasterly group, two high defense terraces protected the rest of the site from attack. The upper slopes of the ridge, close to the various groups, were dotted with house platforms. These, of which there were over 400, were small platforms of stone with a terrace in front of each. Both Cahyup and Chuitinamit have many well preserved standing structures that show a great deal of Mexican influence. A good example of this, which occurs at both sites, is twin temples standing on a communal pyramidal substructure.

Pichec, another hilltop site, lies directly across the valley from Chuitinamit. It is a small group comprising a temple and altar and several low platforms. Toloxcoc stretches along a high ridge about 7 km southeast of Rabinal. There is very little standing masonry left, just low platforms with post holes, small shrines, and considerable terracing. Pachalum is another hilltop site just east of San Jeronimo. Stretching along the crest of a hill about 300 m above the Salama valley, it is a fairly extensive ruin of the type of Chuitinamit. The main plaza has a temple in its center and several altar platforms, and is bordered by long, low, one-room buildings. There is no ballcourt, but there are outlying platforms and terracing. Locally the ruins are known

as "Pueblo Viejo," but as this term is often used for sites lying near villages, it seemed best to distinguish the site by calling it Pachalum after the hill upon which it rests. El Portón, a valley site, is on a national plantation about 1 km out of San Jeronimo on the road to Salama. There is no masonry showing here, only a group of mounds on three sides of a large plaza.

After leaving Baja Verapaz, Smith and Tejeda, accompanied by Miss Proskouriakoff, moved to Néabaj, Department of Quiché, where comfortable quarters in the local pension served as a base for the remainder of the field season. Most of the time at Néabaj was spent in excavating the frontal platform of a large mound in the main group of the ruins of Néabaj. This mound has the same shape as a mound facing it, in which, during the 1946 field season, Smith excavated a corbel-vaulted tomb of the Early Classic period. Leaving Tejeda to find the entrance of the passageway into a similar tomb, Miss Proskouriakoff and Smith visited other sites to gather material for reconstruction drawings.

The first ruin visited was Chalchitan, a valley site in the Department of Huehuetenango. Here the ball-court group, rather than the whole site, was chosen for investigation. In the Sacapulas area of the Department of Quiché the fortified hilltop site of Chutixtiox and the valley site of Xolchun were selected. Throughout the season, when opportunity offered, other sites were visited for the same purpose: in the Ixil area of the Department of Quiché, the ball-court sites of Oncap, Huil, Tzicluay, Vicaveval; in the Rabinal area, Cahyup and Chuitinamit. In Sacapulas two tombs were found, one at Chutixtiox, the other at a new site called Xolpacol, about 6.5 km from Sacapulas on the road to Aguacatán. Unfortunately, both tombs had been robbed, but their shape could be determined; it proved to be very different from that of tombs found at earlier sites, Chutixtiox and Xolpacol being of the late, conquest type. The tombs, which were in structures, had two chambers each, an inner circular one which was the tomb proper, and a rectangular antechamber considerably larger in area. The two parts of each tomb were joined by a doorway blocked by a stone slab.

Returning to Néabaj, after their first absence, Miss Proskouriakoff and Smith learned that Tejeda had uncovered an altar below which was a burial of 11 skulls. He also had uncovered a paved ramp leading downward beneath the frontal platform of the mound. At this point Tejeda left Néabaj to resume his studies at the University of Mexico. He was replaced by Mr. Douglas Binney. Further excavations disclosed that the ramp descended to the entrance of a long passage way leading into a corbel-vaulted tomb similar to the one found in the opposite mound in 1946. Unfortunately, the vault had collapsed, and it was necessary to dig down from the top of the frontal platform in order to

get into the tomb. This required digging a pit 8 m wide and 12 m deep. The tomb, the earliest found, had been placed in sterile ground well below the foundation of the earliest structure.

During the excavation required to get into this tomb, a series of eight tombs and 21 caches was found associated with six superimposed stairways belonging to a sequence of platforms, several of which were painted red. Fortunately the tombs and caches were so stratified that their relative positions in time could be established. They cover a span of some 700 years of occupation, from the Early Classic period through the Postclassic period of Plumbate pottery. The tombs vary in construction. In Early Classic times large chambers were constructed and roofed with corbelled vaults, whereas smaller and narrower tombs were closed with large stone slabs extending from wall to wall. In Late Classic times the large vaulted tombs were abandoned and only long, narrow chambers roofed with large slabs were used. Still later in Postclassic (Plumbate) times, tombs were roofed with wooden beams supporting stone slabs. In all periods multiple burials were the custom.

Furniture from the tombs and objects found in caches vary according to the style of the period with which they were associated. Such material consists of pottery, alabaster and marble vessels, pottery whistle figurines, beautiful jades in the form of beads and carved pendants and plaques, shell ornaments, crystal pendants, pyrite mirrors, flint laurel-leaf blades, copper and gold ornaments, incense burners, and the remains of a codex, part of one page of which depicts a priest or ruler in costume. It is interesting to note that at Nébaj outside influence seems to be from the Maya of the Río Usumacinta area rather than from the Mexicans.

Unfortunately very little architecture was found. The outer structures had been ruined by agriculture, and the inner structures had been cut through or partially removed to put in late tombs. Throughout the work architectural features that came to light and the positions of tombs and caches were recorded on plans and sections by Miss Proskouriakoff. In May she and Binney had to leave, the former to return to the United States. At this time Mr. Gustav Strömsvik joined Smith and assisted him in the completion of the excavations.

During the operations at Nébaj two new sites were visited, Caquixay and Tuchoc. Caquixay is about a two-hour horseback ride east of Cotzal. It is a well preserved site of the Huil type, namely, a ballcourt, and adjoining plaza with an altar platform in the center of the latter. The ballcourt is of the open-end variety and had the stucco remains of what appeared to be a human head with feathered headdress in the center of either playing wall. Tuchoc, about halfway between Caquixay and Cotzal, is a site of the same type. Other

new sites were located through the kindness of Colonel Arthur Binney, United States Naval Attaché in Guatemala, who took Smith on several flights over the San Andres Sajcabaja area. This area, which lies about 27 km northeast of Quiché, consists of a large open plain about 1200 m above sea level. As a result of the survey six sites, which from the air appear to be in a good state of preservation, were located on the plain.

Owing to the length of time taken in the excavations at Nébaj, several investigations had to be postponed until some future date. Among these are a ground reconnaissance of the Sajcabaja area, the mapping of the fortified site at Xolpacol, and an attempt to find at either Chutixtiox or Xolpacol an undisturbed late tomb of the type which was noted this season but of which both examples had been robbed. The discovery of such a tomb at one of these conquest-period sites would be of the greatest importance, as it should contain objects in use shortly before or at the time of the conquest.

22.12.

A. LEDYARD SMITH
Guatemala Highlands

YB 48:224–229, 1949

The 1948–49 field season was the final of four seasons devoted to archaeological reconnaissance in the Guatemala highlands. As in previous years, the main purpose of the expedition was to obtain as much information as possible in a minimum period of time and with little excavation. In most cases sites were roughly mapped, detailed measurements were taken of individual buildings, a photographic record was made, and pottery was collected. In some instances perspective sketches were made of whole sites or of individual groups. The season included expeditions to sites in five areas: Sacapulas, Nébaj, San Andrés Sajcabaja, all in the Department of [El] Quiché; various sites in the Department of Alta Verapaz; Mixco Viejo in the Department of Chimaltenango.

Mr. A. L. Smith, assisted by Sr. Gustavo Espinoza, began the season at Sacapulas and visited three sites: Chutixtiox, Xolpacol, and Chuchun. At Chutixtiox, a late hilltop site, a tomb was found associated with an early structure. Unfortunately it had been robbed in

ancient times, but the excavation yielded a few objects from the tomb and from the entrance.

Xolpacol, also a hilltop site, proved, although small, to be extremely interesting. Among its 10 structures were a well preserved late-type ballcourt, a small round platform supporting a round superstructure with four doorways, and a low platform upon which rested twin temple mounds. The main temple mound stood in the center of a small plaza. It had been dug into and a tomb exposed (YB 46). A very good sample of pottery was recovered from the surrounding fields and down the steep slopes which had been used as a refuse dump.

Chuchun is a small valley site. Of the eight structures noted, the most important were an open-end ballcourt and two fairly large temple mounds. A small surface collection of pottery was recovered.

Leaving the Sacapulas area, Smith, accompanied by Sr. César Tejeda, assistant archaeologist, and by Mrs. Smith, moved to Néabaj. For the remainder of the field season Mrs. Smith took charge of the food and the gathering of surface pottery collections. While in the Néabaj area time was found to visit Finca San Francisco, belonging to the Brol family; from here the ruins of Chikal were visited.

The major effort at Néabaj was the further investigation of the large mound excavated during an earlier field season [Chapter 22.11]. A tomb was found that proved to be of the same ceramic period as the earliest tomb previously discovered, Late Classic or early Late Classic. The grave was relatively rich in furniture, and additional material was found in the dirt that had caved in from the sides of our original excavation. Before leaving the site, we completely filled the hole.

Two small groups of mounds just north of the main ruins of Néabaj were mapped. Both groups have open-end ballcourts leading into small plazas with an altar mound in the center, the ballcourt being the principal structure in each group.

The site of Chikal, which is of the Huil type, open-end ballcourt and adjoining plaza with an altar in the center of the latter, is in a very poor state of preservation. The ruins are used as a corral, and stones from the structures have been removed to build walls. No map of the ruins was made, as Burkitt had published one. No pottery was found at the site.

From the Néabaj area the expedition moved to San Andrés Sajcabaja. This area had previously been reconnoitered from the air [Chapter 22.11]. Eleven sites were visited: La Lagunita, Xepom, Xolja Alto, Xolja Bajo, Pantzac, Patzac, Llano Grande, Los Cimientos, La Iglesia, Chusap, and Xabaj. These were located on a tracing of a map of the municipality.

La Lagunita, a large site, consists of two groups separated by a deep ravine. Group A has 14 struc-

tures, an enclosed court, and several plazas. In the main plaza beneath is a plain stela, beneath which someone had dug. Six of the mounds are large, but no traces of superstructures were found. Group B, with 13 structures, has two possible ballcourts, one with open ends, the other closed but with no apparent end zones. The rest of the structures are platforms surrounding courts or small plazas. Both groups are surrounded by deep ravines and lend themselves to defense. Pottery from the site seems to place it in the Late Classic period.

Xepom, Xolja Alto, and Xolja Bajo are small sites. Xepom and Xolja Alto are on the tops of hills overlooking the Río Agua Caliente; Xolja Bajo is in the river valley. Very few architectural details of interest were found and only a small amount of pottery was collected. From the sherds recovered, Xolja Alto and Xolja Bajo appear to have been occupied in Late Classic times.

The largest site visited in this area was Pantzac. The ruins are not unknown, having been mapped by Sapper and briefly described by Maudslay. Sapper's map is extremely accurate and needs few changes. There are 38 mounds still in existence, but Sapper shows others which have been razed; many of the architectural details that he indicates have long since disappeared. The masonry is of well cut and faced blocks which the inhabitants now living in the ruins use to build their houses and fences. The site divides itself into about five groups containing temple mounds and long structures surrounding plazas and courts, altar mounds, platforms, and a sunken court. There are two ballcourts, one with open end zones and an adjoining plaza not unlike the Huil type, another with end zones probably closed with low walls. Pottery, found in quantities in the surrounding fields, places the occupation of the site in Plumbate times. Although probably not built as a defense site, Pantzac lies on a plain surrounded by deep ravines which would afford easy defense.

Patzac, like Pantzac, is surrounded by deep ravines. It is a large site having 34 structures. These are mostly in the two main groups, the rest being in scattered groups of two and three mounds. Each of the main groups has a ballcourt with closed end zones. Other structures take the form of temple pyramids, platforms, and altars. Several of the structures support low walls of superstructures. The pottery collected shows that the site was occupied at the time of the conquest.

Llano Grande lies in a plain, and the site definitely was not built with any idea of defense. The ruins consist of a large rectangular platform, reached by a stairway on its south side, and supporting four mounds and a sunken court. The last, which is at the west end of the platform, is probably a ballcourt. To

judge by the pottery recovered, the site was probably occupied during the Late Classic period.

The best-fortified site visited in the area was Los Cimientos, completely surrounded by steep ravines, the only entrance being over a causeway. Nine structures at the highest point comprise the ceremonial center. Eight of these follow the edges of terraces and form the sides of a small plaza; the ninth structure, a temple mound, is in the plaza. Two of the nine structures are temple mounds, seven are low platforms, most showing signs that they once supported superstructures. The main feature at the site is the terracing on its east, south, and west sides. The terrace walls are built against natural levels running in all directions and varying in height. Reaching to the side of the ravine, the terraces are quite extensive and may once have been used as sites for houses of perishable material. Surface pottery is scarce, but a small collection places Los Cimientos in the conquest period.

La Iglesia, the main structure of which has been turned into a crude modern church, has two groups. Group A lies on a large oval hill which rises about 50 m above the surrounding plain. It consists of a rectangular court surrounded by a low wall with an entrance in the south side. All but one of four platforms in the court carried stone superstructures. The superstructure of the largest was of great interest, as the walls stood to considerable height in some places, and the method of construction could be examined in detail. A good sample of pottery of the Plumbate period was obtained from this group. Group B is on the level of the plain. It is made up of a plaza with a large rectangular platform on each of three sides. No masonry was showing, and there was no evidence of superstructures.

Chuscup was visited because of a reported subterranean passage that had never been explored. It turned out to be a bottle-shaped hole in the center of a small field on a hill near the Río Agua Caliente. In shape it resembles a chultun, having a narrow neck for an entrance, with stones around the top, which was covered with a stone lid. Nothing was found in it and its purpose could not be determined. No structures of any kind were found in the vicinity.

The last site visited in the San Andrés Sajcabaja area was Xabaj. It is a small group of three platforms strung out along the top of a hill high above the plain. The platforms, which are almost square, still support the remains of superstructures. Two of the structures had each a small modern shrine on top, and a third had 6. Several of the shrines contained small carved monuments. No pottery was recovered. According to the local inhabitants, Xabaj is an important place of worship today.

The fourth expedition was to Alta Verapaz, the personnel being Mr. and Mrs. Smith, Mr. R. E. Smith,

and Dr. Stephen Borhegyi. Ceramic studies were in the charge of R. E. Smith and are reported by him below. Perspectives sketches of ruins were made by Borhegyi. The following sites were visited: Esperancita, Tampoma, Omaxa, Canchunac, Las Tinajas, Pueblo Viejo, Chicuxab, Valparaiso, and Chinchilla.

The expedition's first base was Finca Mocca, belonging to Mrs. Robert Hempstead. The finca lies northwest of La Tinta, a village on the Río Polochic. The first ruin visited by Esperancita, a small site consisting of eight mounds and several terraces on top of a sloping ridge. The ridge rises in natural terraces, the upper three having been artificially leveled and faced with rough stone slabs. Large stairways lead from one terrace to another. The lower terrace supports the main group. Here six long low platforms surround a small plaza with a rectangular platform in the center. The second terrace supports a long low platform. There were no structures in the third. The platforms are not oriented to one another, as they follow the contour of the ridge. A sketch was made of this site.

Tampoma has five small groups spread out on the flat valley floor. A small river, the Tampoma, flows through the ruins to join the Polochic. The largest group has what appears to be a ballcourt with an adjoining plaza with long low platforms on three sides. Off to one side is a low mound with a plain stela and altar in front of it. The other groups had three or four mounds each, surrounding small plazas.

At Omaxa, close to Tampoma, are several small mounds and one large one. Unfortunately the site was so overgrown that no work could be done. Canchunac, west of Finca Mocca, consists of a series of terraces and one mound.

After leaving Finca Mocca the expedition moved to Finca Las Tinajas on the south side of the Río Polochic, where two ruins, Las Tinajas and Pueblo Viejo, were visited.

The ruins of Las Tinajas, also called Tzesac and located on Sapper's map as Chacujal, are close to the Río Tinaja, which flows into the Polochic. It is possible that this may be the Chacujal mentioned by Cortés in his fifth letter to the Emperor Charles V. It is a large site, at present badly overgrown. Twenty-six structures were found, a number of which supported the remains of stone superstructures. Two temple platforms stood in the center of a large plaza. The buildings were constructed of a hearting of clay and water-rolled stones faced with thin stone slabs laid in clay. It is worthy of note that no clay or thin stone slabs seem to occur in the vicinity of the ruins. A sketch was made of the site.

Pueblo Viejo is an extensive ruin not more than a kilometer west of the ruins of Las Tinajas. The mounds are piles of water-rolled stones with only a few instances of thin slabs around the base. It is very pos-

sible that these mounds formed a part of Las Tinajas that was never completed. No map was made of Pueblo Viejo because of its overgrown condition.

The expedition next proceeded to Finca Seamay and thence to Finca Arenal, both of which belong to Mr. George Koester, and which lie north of the Río Polochic not far from the village of Senahú. At Arenal two sites, Seacal and Chijolom, were visited.

Seacal lies on top of a steep hill covered with outcroppings of rock of the type used in the masonry at the site. The main feature of this small ceremonial group is a rectangular sunken court with sides of large, beautifully cut and faced stone blocks. The court is surrounded by rectangular platforms on the ground level above it. A sketch was made of the site.

Chijolom, a small group in which the ballcourt is the main feature, lies in the saddle between two hills. The ballcourt is the open-end type and has its sides built against two hills. On one side terraces and stairways rise further up the hill. Beyond a rectangular platform at either end of the ballcourt, terraces extend down into the ravines. The masonry, the most beautifully cut and fitted seen in any part of Guatemala, was laid without the use of mortar. A sketch was made of the group, showing details of stonework.

After leaving Arenal the expedition moved to Cobán, once more as guests of Mrs. Hempstead. Three sites were visited: Chichén, Santa Elena, and Chicuxab.

The ruins of Chichén are about 30 m above the north side of the Río Chichén. Almost all the 17 structures are oriented to one another and are grouped around three plazas. There are rectangular platforms, altar platforms, a temple mound, and two open-end ballcourts. The last are very similar to the ballcourt at Chijolom. No evidence of superstructures was found. A sketch was made showing the entire site.

Santa Elena, south of Cobán, is a small valley site of four platform mounds, three of which are oriented around a small plaza. The fourth mound lies to the north of the plaza group. Chicuxab, a three mound site, lies in a hollow in the hills. The three platforms are almost shapeless from having been plowed over.

After leaving Cobán the expedition returned to Guatemala City via Salama. Between Cobán and Salama two sites, Valparaiso and Chinchilla, were examined.

Valparaiso, a small site lying north of the Río Cobán, had been visited by Shook and Smith some years ago, when a collection of surface pottery was made and the site was roughly mapped. We now attempted to obtain more pottery, but the owner was away and the resident Indian family would not permit any work.

The two groups which make up the ruins of Chinchilla are on the slopes of two adjacent hills on the north side of the Río Frio. The site was previously seen

by Dr. Kidder and at that time was in a much better state of preservation. The main group consists of five structures: four platform mounds are oriented around the four sides of a small plaza, in the center of which is a large temple platform. The other groups consists of three small mounds.

The final trip of the season was by Mr. and Mrs. Smith and Borhegyi to Finca Las Pilas, belonging to Sr. Francisco Martínez del Rosal, in order to examine the ruins of Mixco Viejo, a conquest site mentioned in the early accounts. The ruins have been mapped by Sapper. Mixco Viejo consists of 12 groups spread along the flat top of a ridge completely surrounded by steep ravines. It is a well fortified place which can be entered only by a steep narrow trail, easily defended. The larger groups consist of structures surrounding, in each case, a plaza, often with a temple mound or platform in the center. The structures are not oriented to one another because they follow the edges of the ravines. In many cases the upper edges of the ravines are faced with stone. On the south side there are natural terraces where the abundance of refuse indicates that thus may have been an area where houses of perishable material once stood.

The 68 or more structures at the site consisted of temple platforms, long platforms with three or more stairways on one side, altar mounds, long low rectangular platforms, twin temple platforms on a single platform, and two ballcourts. The last were of the conquest type with closed end zones and a stairway at the center of each end. Although many of the structures must have had superstructures, no evidence of them was found. A sketch was made of Group B, one of the largest groups that contained the greatest variety of structures. A large surface collection of pottery was recovered, but nothing was found in the several pits that were dug in platforms. Surface pottery contains some Early Classic, a good deal of Late Classic, and an overwhelming amount of conquest period wares. No Plumbate period pottery was found.

ROBERT E. SMITH

Guatemala Highlands

YB 48:229–231, 1949

The pottery findings of the Alta Verapaz archaeological survey were quantitatively small but typologically

significant. The hilltop sites, Seacal, Esperancita, Chijolom, Chinchilla, and Samac, were especially lacking in potsherds with the exception of Seacal, which contributed about a hundred. These sites, including the ballcourt site of Chijolom, probably served as shrines, and therefore ceremonial pottery normally associated with tombs and caches was mostly used. In their function the Alta Verapaz hilltop sites differ markedly from those of other sections of the country, which appear to have been fortified retreats and where quantities of utilitarian as well as more elaborate pottery are found.

A tomb with skeleton, six pottery vessels, and bone ornaments was uncovered at Seacal. Two of the vessels equate with Tepeu 3 types. A cache in Mound I at Esperancita contained two pottery vessels suggesting a Tepeu 1, 2-Chipoc-Chamá 3, 4 Alta Verapaz II horizon. In addition, some 60 sherds were recovered from three sizable trenches. None were found on the surface. At Chijolom a trench was dug across the center of the ballcourt and a pit was sunk into the center of the northeast platform mound, but the only place from which potsherds were recovered was a low terrace off the southwest end of the ballcourt, where there was a vegetable garden. Here some 30 sherds were gathered from the surface. These indicate a Tepeu 3 to Tohil, or even later, horizon. The pottery picked up from the surface of the larger group at Chinchilla included two faceted, red ware, Z-angled sherds from Miraflores-Chicanel type. The other eight fragments recovered were too small and weathered for identification. A tomb, excavated on Finca Samac many years ago, included a skeleton and five pottery vessels. One of the latter is a Tohil Plumbate specimen which dates this grave as Postclassic-Tohil phase according to Dr. Wauchope, or as Alta Verapaz III according to Dr. Butler. On top of the hill upon which the tomb was discovered we were fortunate in finding a ready-made cut, exposing a section filled with potsherds ranging from Chipoc (Tepeu 1, 2-Chamá 3, 4-Alta Verapaz II) to Yaqui, the latest preconquest ceramic phase.

The valley sites, Las Tinajas and Tampoma in the Polochic valley, Chichén, Chicucab, Santa Elena, and Valparaíso in the Cobán area, as a rule were well supplied with potsherds. The exception was Las Tinajas, a large site where we dug a deep pit into the center of a long low platform mound and found a handful of unidentifiable sherds. Pits were dug throughout the main plaza, from which a total of one potsherd and an effigy-head foot resulted. At Tampoma two pits were

dug, one into a rock pile mound, the other under an unmarked stela. Most of the identifiable sherds from the former belong to the Chipoc phase, as do those from the latter pit, which also contained jade (two tubular beads and three very thin flat perforated ornaments) and a pyrite mosaic mirror fragment. Most of the sherds from this site were picked up from the surface, an ancient river bed. Because of the water worn or generally weathered condition of these fragments, much of the material is unidentifiable, but a quantity of Chipoc types were recognized. It is likely that further study will bring to light later horizons.

In the Cobán area the largest site observed was Chichén. Here we dug pits into three mounds, trenched across the center of the main ballcourt, and collected surface pottery. Mound III contained the earliest (Chicanel) as well as the latest recognized (Tohil) pottery. Undoubtedly the site was occupied up to the conquest, and further study presumably will prove this. Chichén is a present-day pottery-manufacturing center. Chicuxab is a small site, but the surface is literally bristling with potsherds. We did no digging here, but picked up a carefully selected collection, containing largely Chipoc types besides a few Tzakol-type and Tohil pieces. Another small site, Santa Elena, close to Chicuxab, had an abundance of pottery on the surface and inside small platform mounds, two of which we trenched. The only Chicanel-type sherds were found on the surface. The mounds and surface yielded Tzakol and Chipoc types in considerable quantity and probably later types. At Valparaíso a surface gathering contained a few Tzakol and Chipoc types and an abundance of unidentified fragments which probably form part of later cultures.

From this survey we find that in the Alta Verapaz we can recognize various phases which closely parallel those suggested by Dr. Butler (1940). Dr. Butler's work, however, deals for the most part with the Chixoy drainage area and includes sites in the western part of the Alta Verapaz or farther west in the Department of [El] Quiché, an area not touched in this survey. In order to keep the ceramics of the two areas separate, we are proposing new ceramic phase names for central and eastern Alta Verapaz: Chipoc (Tepeu 1,2; Pokom; Chamá 3,4; Alta Verapaz II; Late Classic), Seacal (Tepeu 3), Samac (Tohil; Chimal 2; Alta Verapaz III; Postclassic). The Preclassic and Early Classic, as well as the later phase corresponding to Yaqui, will be named when further knowledge as to the distribution of the wares of these periods in the Alta Verapaz is available.

23.0. KAMINALJUYÚ

Kaminaljuyú has been known for a long time and was visited by Alfred P. Maudslay at the end of the nineteenth century. He later published a plan of the site and a photograph of the mounds. Extensive excavations were undertaken at the site by the Carnegie Institution of Washington in 1936 and the work continued for several years. Reports were subsequently published on the excavation of Mounds A and B (Kidder, Jennings, and Shook 1946), D-III-13 (Berlin 1952), and E-III-3 (Shook and Kidder 1952). Their efforts constitute the earliest major archaeological research on Kaminaljuyú, and all were last minute efforts to salvage structures in immediate danger of destruction. The results of these excavations should be considered as one of the great achievements of American archaeology because archaeological work at Kaminaljuyú established for the first time a long consecutive chronological sequence for an area within the Guatemala highlands and also one of the most complete local sequences in Mesoamerica. It modified concepts about the nature of the culture of the Preclassic, or Formative, period. At least half of the 200 mounds were discovered to be Preclassic in date, including some of the largest struc-

tures of the site. The scale of the architecture and the wealth of tombs located within the mounds demonstrated conclusively that archaeologists had underestimated the size and degree of internal social differentiation of Preclassic societies. Prior to Kaminaljuyú, the Preclassic was conceived of as a period of socially homogeneous, sedentary folk agricultural societies. Mounds A and B were of Classic date and the association of Maya and Teotihuacán pottery in the same tomb completely altered the picture of the chronological interrelationships of the various Classic civilizations of Mesoamerica. Prior to the Carnegie excavations most researchers assumed that Classic Maya civilization started earlier and stimulated the growth of other Mesoamerican Classic civilizations. The excavations revealed the contemporaneity of the various regional cultures and in fact meant that much of the development of Teotihuacán was Preclassic in a chronological sense. This in turn has stimulated considerable controversy. A major discovery in Mounds A and B was the extraordinary impact of Teotihuacán on Kaminaljuyú in Classic times. The tombs contained copies of or imported Teotihuacán pottery and the pyramids that contained them

were copies of Teotihuacán architecture, including the typical specialized *tablero-talud* moldings. This discovery immediately initiated a series of controversies.

In the late 1960s, the Pennsylvania State University sponsored work at the site, directed by William T. Sanders and Joseph H. Michels. A series of monographs on the site was published by Pennsylvania State University in the 1970s. In 1994 Kaminaljuyú was made an archaeological park, and Guatemala Instituto de Antropología e Historia began a project on one of the few structures still standing.

23.1.

ALFRED V. KIDDER AND
OLIVER G. RICKETSON
Kaminaljuyú
YB 35:130–131, 1936

To the great aggregation of mounds on Finca Arevalo, Finca Miraflores and other farms in the outskirts of Guatemala City, the above name has been given by the Sociedad de Geografía e Historia of Guatemala. At the suggestion of Lic. Antonio Villacorta, Minister of Public Education, excavations were undertaken at one of these mounds. The structure proved to consist of four small pyramids built one over the other, the innermost and the second of adobe, the third and fourth of tufa blocks laid in mud mortar.

The eastern half of the complex was excavated, the operation yielding large rectangular pits lying immediately to the east of the mound. They contained the skeletons of persons of importance, accompanied by lavish offerings of implements, pottery, and jadeite ornaments. Some of the pottery appears to bear close resemblance to that of Uaxactún, some to that of Teotihuacán in Mexico. Final description of the pyramids and conclusions regarding the cultural relationships of the associated tomb material must await excavations planned for 1937, when, it is hoped, the remainder of the mound may be cleared and a fourth tomb, believed to lie below the second pyramid, may be investigated. An illustrated preliminary report has been issued as a press-release of the Institution.

Mrs. Ricketson carried on studies of the early pottery collected in 1935 at the Finca Miraflores.

23.2.

ALFRED V. KIDDER AND
JESSE D. JENNINGS
Guatemala Highlands
YB 36:143–144, 1937

Kaminaljuyú, a great aggregation of mounds in the southwestern outskirts of Guatemala City, has long been known to archaeologists and has long been believed important because Gamio’s excavations of 1925 had revealed the presence there of a presumably early culture; because of Lothrop’s identification of sculptures indicating influence from the Maya Old Empire; and, because, being situated athwart probable highland routes of migration and commerce, it might be expected to yield trade objects valuable for determining cultural and chronological relations between various Middle American civilizations. The Institution began work here in 1935 with excavations to check Gamio’s findings. Much ceramic material from the early period was recovered [Chapter 22.3]. In 1936 a mound on Finca La Esperanza was partially excavated [Chapter 23.1]; it was completed during the part season and the frontal terrace of a second mound was investigated.

Mound I proved to consist of eight structures, built one over the other. The two innermost were rectangular, vertical-walled platforms, the first of masonry, the second of adobe; the next six were truncated pyramids, the first four of adobe, the last two of water-rounded tufas laid in adobe. The total height of the complex was about 6 m.

The top of each pyramid had been reached by a stairway, and the summit platform of each had supported a superstructure, presumably a small temple. The current temple had been razed at each successive enlargement of the mound; that surmounting the outermost pyramid either had never been erected or had completely disappeared through erosion. Only the stairway of the last adobe pyramid had escaped destruction; buried in its exact center, halfway up, was a boulder of crude jadeite weighing some 200 pounds.

Associated with Mound I were six tombs, two of which, covered by the frontal platforms of the last two structures, were excavated in 1936; the other 4, lying below the mound, were cleared during the past season.

Of Mound II only the frontal platforms were excavated. Like those of Mound I, they covered tombs, two of which could be assigned to the two major building stages of the platform; the third was intrusive.

All nine tombs were rectangular pits, sunk from 1 m to nearly 5 m into subsoil. Some certainly, all probably, had been log-roofed. Each contained a principal

skeleton lavishly adorned with jade, mosaic mirrors, and shell ornaments, and accompanied by the skulls or complete skeletons of several other individuals, presumably slaves; much mortuary pottery was present, as well as remains of elaborate offerings of textiles and other perishable objects.

Interments and accretions to the mounds were apparently correlated, and definite connection between certain tombs and certain structures could be determined. Relative uniformity of funerary practice and close similarity between pottery from all graves indicates a short time-span for the entire series. The pottery evidences trade relations with northern Petén during the Tzakol period (middle to late Old Empire) and with Teotihuacán, Mexico.

At Kaminaljuyú three ceramic phases have so far been identified: Miraflores, early, possibly akin to the Mexican Archaic; Esperanza, the phase of the mounds and tombs, contemporaneous with the Maya Old Empire; Pamplona, crude, late, as yet unrelatable to any other group. Surface sherds from elsewhere on the site suggest presence of additional phases, and raise hope that it may eventually be possible to trace a long, continuous local evolution whose stages can be fitted into the larger scheme of Middle American cultural development.

23.3.

ROBERT E. SMITH

*Minor Archaeological Studies
at Guatemala*

YB 37:159, 1938

Small clay figurines, for the most part in the form of human effigies, are among the most characteristic and, archaeologically, the most significant remains of the so-called Archaic culture of Middle America. They were also produced in large quantities by the Maya, the Toltec, the Aztec, and other people of later times.

Mr. Smith, in his work upon the pottery of Uaxactún, has been giving special attention to the figurines from that site. The earliest figurines of Uaxactún have proved to be similar to specimens from apparently very old cultures in the Guatemala highlands; and these, in turn, seem allied to the Archaic figurines of Mexico. Mr. Smith has accordingly been led to the

making of a comparative study of all such material, that from Mexico as illustrated in the many publications of Vaillant; that from the Guatemala highlands comprising the collection made by Dr. Ricketson and the Chairman in 1935 at Finca Miraflores, and by the Chairman in 1936 and 1937 at La Esperanza, both localities which form part of the great archaeological site of Kaminaljuyú.

The Kaminaljuyú figurines were found by Mr. Smith to include several distinct types. But the specimens from La Esperanza having come from disturbed deposits, and those from Miraflores from a very small excavation provided no information as to whether the observed types were contemporaneous variants or whether they represented a stylistic sequence.

In order to gather further data Mr. Smith excavated a new and larger section at the Finca Miraflores, isolating a square column of earth, recording its layers, and collecting all material in stratigraphic order. Great numbers of potsherds were recovered which add significantly to our knowledge of the early ceramics of the region. The figurines, of which over 50 came to light, are at present being studied by Mr. Smith.

Mr. Smith also made a trip, during the spring, to Tiquisate on the Pacific coast plain of Guatemala, where the extensive operations of the United Fruit Company have led to discovery of many archaeological remains. These have been noted, and arrangements have been made with the Company officers at Tiquisate for notification of the Institution's office in Guatemala City of further finds.

23.4.

EDWIN M. SHOOK AND

A. LEDYARD SMITH

Guatemala: Kaminaljuyú

YB 41:263–267, 1942

In 1936 and 1937 excavations were carried on at two mounds of the great archaeological site of Kaminaljuyú in the outskirts of Guatemala City [Chapters 1.21, 22.3, 23.1]. One of the mounds (A) was completely dissected. It proved to contain eight superimposed structures and to overlie six pit tombs rich in pottery and jades. The body of the second mound (B) was not investigated, but three tombs were found below its frontal

platform and a modern cut on one side indicated the probable presence of several structures built, as in Mound A, one above another. In the course of preparing the results of the above work for publication, it became obvious that more data were needed on several important points concerning architectural and mortuary practices. It was therefore decided to excavate Mound B, a task undertaken by Mr. Shook and carried out from November 1941 through May 1942.

The mound before excavation was a conical hill-ock some 35 m in diameter by 7.5 m high. A vertical slice had been cut, in recent times, from its western slope; and, some years before, a deep, wide trench had been run in from the southeast by treasure hunters. Mr. Shook's opening trenches were pushed inward from the north and south, these sides being chosen because the later structures in the mound were known to face west, and it had been learned, during the work on Mound A, that tombs and caches, stairways, and other important architectural features were to be found on the front and could more safely be reached by lateral than by frontal approaches. The south trench at once encountered the basal step of a pyramidal substructure of puddled clay faced with a layer of lumps of pumice and coated with *piedrin*, an almost concrete-hard mixture of lime and small pebbles. The trench was pushed through this, revealing a second building of identical construction, which in turn was penetrated as far as a third building of pure adobe. There was thus disclosed a sequence corresponding to that found in Mound A, whose two outermost elements had pumice and clay heartings with *piedrin* finish, the third being of adobe.

At this point it was felt that enough was known of the mound's make-up to permit the frontal features to be investigated. The basal step of the outermost building (Structure 5 in the final enumeration) was accordingly followed around the southwest corner and across the western face to its abutment against the remains of the frontal stairway. The basal step was also located on the north and followed around the northwest corner to the stairway. The same method was employed in outlining Structure 4, and in laying bare the south side of the adobe pyramid, Structure 3. At the same time a third penetrating trench was run in from the east, encountering and passing through two more adobe structures, nos. 2 and 1.

As to Structures 1 and 2, little was learned, for they were seen only in median section in the sides of the narrow penetration trench. They appeared to have been low pyramids, parts of which had been cut away in the course of building the later units of the complex. Structure 3, however, was relatively well preserved. It was an adobe pyramid with basal measurements of about 30 by 30 m, a broad adobe stairway with heavy

balustrades mounting its western face. The upper part of the stairway had been destroyed by the pot hunters' trench, but a small area of the summit platform remained.

Structures 4 and 5, though inferior in construction to the corresponding units of Mound A, yielded the hoped for information as to the pumice and *piedrin* type of building. It was learned that it had a topped by low basal step, a lower-sloping zone topped by a slab-supported cornice, and a more nearly vertical second zone divided by moldings into rectangular panels. At the front a stairway mounted to a jutting platform, on which there apparently was located a small shrine. A second flight of which only traces of the lowermost steps remained, led upward, doubtless to a temple on the summit platform.

Two tombs were found: a small one south of the foot of Structure 5's stairway, and a very large one in front of the foot of the stairway of Structure 3. The small tomb contained the skeleton of an aged male, the bones of a child (probably a sacrifice), some jades, and a number of pottery vessels. The large grave was evidently that of an important personage, as it was more lavishly stocked with mortuary equipment than any of the other tombs so far opened at Kaminaljuyú. The principal occupant, seated cross-legged in the center of the tomb floor, had been literally covered with ornaments of jade and shell; a necklace of 280 jade beads was about the neck. In front of the body was a pile of very fine pottery, many of the pieces coated with stucco and beautifully painted. The skeletons of three young persons, evidently sacrificed at the time of their master's burial, lay toward the walls of the tomb. Near one of them was the finest single object recovered, a pyrite-incrusted plaque whose slate backing bore an intricate carving, the central elements being two small figures standing on either side of an altar, from which rises what appears to be a conventional tree.

Although the finds in this tomb were most spectacular, the most important results of the Mound B excavation were the data recovered as to architecture and as to the succession of pottery types. Great numbers of sherds were found in the fill. These were largely of the Esperanza phase, contemporaneous with the erection of the structures, but among them were many fragments of Miraflores pottery. The latter, representing the oldest ceramic horizon so far identified at Kaminaljuyú, had, of course, been scraped up with earth used for the fill of the various structures. After the mound had been abandoned as a place of worship and had fallen more or less into ruin, there accumulated on and about it a heavy stratum of occupational debris containing pottery of two post-Esperanza phases which have been called Pamplona and Amatlé. Although stratigraphic conditions were not clear, there

is little doubt that Amatlé is the older of the two. One component of the Amatlé phase is Plumbate Ware, mostly in simple cylindrical forms. Similar Plumbate was found in 1940 by A. L. Smith at San Agustín Acasaguastlán on the Motagua River, and more came to light in J.E.S. Thompson's excavations of the past season at El Baúl on the Pacific coast plain. When these and other ceramic materials from highlands and lowlands have been studied and compared, it seems probable that the chronological and commercial relations of several important ancient Guatemalan cultures will become clear.

During the mapping of Kaminaljuyú in former years there had been noted at least nine constructions which, because of their elongated rectangular form, were surmised to be ballcourts. In order to test this supposition, A. L. Smith, in 1941, ran a trench across the middle of one of the largest. The finding of two tenoned stone parrot heads, analogous to those of the Copán ballcourt, and of traces of sloping benches paralleling a playing alley settled the matter conclusively.

During the past season further excavation was carried on here, and two smaller courts were investigated. The original 1941 trench in the large court was reopened and sunk to a depth of about 5.5 m before sterile natural deposits were reached. Directly below the northern long wall, Mr. Smith exposed parts of two deeply buried earlier constructions. The upper one was of red-painted adobe, apparently with low vertical terraces. Its upper parts had been cut away in ancient times. An adobe floor, also painted red, extended outward from its base. Farther down was the southeast corner of a very well preserved building, probably a substructure. Its basal terrace had borne slab-supported moldings, torn away when the building was buried, but it, and what remained of a second terrace, were still covered with smooth, hard, red-finished *piedrin*. Well underneath this was a floor of packed adobe, under which, to subsoil, a distance of nearly 2 m, the deposit contained only Miraflores pottery, the earliest type so far found at Kaminaljuyú.

By the time subsoil had been reached, the rainy season was about to begin. Work was therefore suspended, but the trench was fenced and left open in case it should be possible to push the operation farther at some future time. Although removal of the tremendous overburden would be a long and costly undertaking, the investigation of the early buildings and of what may well lie below and behind them would undoubtedly yield invaluable archaeological information. We already know that there is a direct superposition of three types of structure and a stratification of Miraflores, Esperanza, and Pamplona-Amatlé pottery. Because of the depth of the deposit and the scaling of several of its horizons by floors, there is likelihood of

recovering unmixed samples, some of them perhaps exemplifying hitherto unknown transitional ceramic periods. Furthermore, the lowest floor may be connected with a structure dating from Miraflores times. The discovery of such a building would be of the greatest interest, for Miraflores structures, presumably ancestral to all later architectural developments in this region, are still entirely unknown.

While work in the deep central trench was going on, a pit was sunk in the southwest corner in a vain search for the tenoned stone head which, on the analogy of the Copán ballcourt, should have been found there. The digging, however, revealed, below the level of the court, a *piedrin* floor pierced by several large post holes, which indicated the former presence there of a building of perishable materials.

The second ballcourt investigated formed part of a small group just to the east. A trench was dug across its short axis, a little north of the center in order to cut into a mound resting on the western wall of the court. The upper part of the wall and the face of the mound proved to be terraced and to bear a *piedrin* coating.

The transverse trench, again carried to subsoil, yielded evidence of a long series of structural events, involving two rebuildings of the court; an abandonment during which a humus layer was laid down; and the excavation, perhaps through a still earlier fill of a pit in whose bottom was a drain, slab-floored and walled but without capstones. A tenoned human head of stone came to light in the western extension of the trench.

The third court lies a considerable group well to the east in a district called La Granja, where a real-estate development is now being undertaken. As part of the "improvement" a road was run through the court, cutting both end walls and passing down the long axis of the playing alley. This permitted observation, with relatively little digging, of the closing walls and the alley. The dimensions of the alley were determined to be 33 by 7 m. Remains of an earlier construction were laid bare. This, razed almost to ground level when the Court was built, had originally been a multi-chambered affair without supporting platform. In its *piedrin* floor were postholes and on it were butts of several free-standing walls of mold made adobes faced with pumice blocks and *piedrin*.

A number of finds were made at this court. Directly under the southeast corner of the playing alley were two plain red ware bowls set lip to lip, probably a dedicatory offering. Near the center was a large tenoned stone snake head, which had obviously slipped down from the north-central wall. Several other heads and pieces of broken sculpture had come light during the digging of the modern road. In the center of the court Mr. Smith encountered a filled pit which, seeming

to be ancient, was believed to have served a drain or sump. Well below the level of the playing alley, however, were the most completely rotted bones of a horse and below them, the crushed remains of two, pottery water jars. The horse bones of course, proved the pit to be post-conquest, but their condition argued for very long burial, and the jars, when restored were found to be of an unknown type, perhaps ancestral to present-day Chinautla pottery. They are, in any case, the oldest modern vessels so far collected.

To sum up: Mr. Smith's investigations made it clear that the nine or more long rectangular constructions at Kaminaljuyú are ballcourts, and have permitted identification as such of many similar ones at other sites throughout the valley of Guatemala. The ballcourt, indeed, is shown to have been perhaps more abundant in this region than in any other part of Middle America. As to the details of construction, data are as yet not fully satisfactory because, being of pure adobe, the courts have suffered severely from erosion and the growth of forest trees. It is known, however, that the playing alley was long and narrow, and that it had low, sloping side benches. It was closed at either end, thus lacking the expanded end zones characteristic of most other ballcourts. Set opposite each other at the middle of the parallel side walls were two tenoned stone heads, usually parrot or snake, often with a human face in the open mouth. Whether these were placed vertically, as at Copán, or horizontally is unknown, as all were found fallen forward on the side benches. There was no evidence of stone markers in the floor of the playing alley. The courts seem to be sited without regard to the cardinal points.

23.5.

EDWIN M. SHOOK

Guatemala Highlands

YB 47:214–218, 1948

Two of the most significant archaeological discoveries of the past year in Guatemala were made accidentally. The first was in Kaminaljuyú on the outskirts of Guatemala City, and the second, 29.5 km west of the city near Santa Maria Cauque, in the Department of Sacatepéquez.

The latter find was made en route to Tiquisate by Mr. Shook and his assistant, Mr. Henry Morgan, as

they were passing through a new road cut for the Roosevelt Highway, where it skirts the foothills along the west side of the Río Sacatepéquez valley. A low spur of the mountains had been cut to a depth of 4 m below the original surface with heavy road equipment. Prior to excavation, no artificial mounds, pottery fragments, or other remains had appeared on the surface to indicate that a town site once existed there or in the immediate vicinity. About 0.75 to 1 m below the surface, however, a number of ancient pits and graves were encountered. The pits, similar to ones frequently found in Kaminaljuyú and Salcajá, were oval in profile, varied from 2 to 3 m in depth, and were filled with ancient rubbish. Many graves were disturbed by the heavy machinery, as was evident from the number of freshly broken pottery vessels, human bones, and jade beads scattered along the roadbed. One grave, left partly exposed in section, was excavated by Shook and Morgan. A vertical shaft had been sunk to a depth of 2.5 m and an adult buried at full length on its floor. Surrounding the body were thin stone slabs set on edge. The left side of the skeleton, the slabs, and whatever mortuary furniture existed on that side had been swept away by the bulldozers. The remainder of the skeleton was *in situ* with eight pottery vessels aligned at the right of the body, several obsidian lancets, and a single jade bead. In addition to the grave contents, a large sample of pottery and artifacts proved to be Preclassic and to be intermediate between Las Charcas, the oldest phase at present identifiable in the highlands of Guatemala, and the Miraflores phase of Kaminaljuyú. It has been given the name Sacatepéquez from the locality in which it was found; its chronological position between Las Charcas and Miraflores was ascertained by the excavations at Kaminaljuyú described below.

The diagnostic pottery of the Sacatepéquez Phase is a White Ware with medium-textured white paste and a well smoothed, polished surface. Vessel exteriors were often decorated by simple incising, grooving, or modeling, and by plain bands or broad-line geometric designs in red paint. This White or Red on White Ware comprised 55 percent of the Sacatepéquez collection. It occurs abundantly in the Guatemala and Antigua valleys, and has been noted as far west as San Cristóbal in the Department of Totonicapán. Worn fragments came from the fill of Structure E-III-3 in Kaminaljuyú, but no vessel of White or Red on White Ware was found in the richly stocked Miraflores tomb in that structure. Such typical Miraflores features as hairline and coarse incised Brown-Black Ware, Fine Red Ware, "Archaic"-type figurines, effigy rim-heads, and secondary vessel supports were entirely lacking from the Sacatepéquez material. Fragments of metates, manos, and comales indicated that even at this early

date the people were sedentary and had developed a secure economy based on the cultivation of corn.

The destruction of the great archaeological site of Kaminaljuyú on the southwest edge of Guatemala City has accelerated since 1940 owing to the encroachment of the modern city in that direction and to the heavy demand for bricks, tiles, and adobes. The material for these is derived largely from the ancient mounds. Many groups and individual mounds have been removed completely since the Institution surveyed Kaminaljuyú in 1936 and 1939. Recently, the Department of Public Works of Guatemala acquired the largest single mound, Structure E-III-3, for the manufacture of bricks. Last November, after most of the eastern half of E-III-3 had been cut away, the workmen, in making another vertical cut downward from the top of the mound, encountered human bones; pottery and stone vessels, some containing mineral paints; several jade ornaments; and a carved "mushroom" stone. Fortunately, the superintendent of the brickworks, Sr. Moises de Leon, halted the work and reported the finds to the Director of Public Works. The Director in turn advised The Minister of Public Education and the National Institute of Anthropology and Ethnology. Mr. Shook was requested to investigate. The above-mentioned objects proved to have come from a tomb, the most richly stocked to be unearthed to date in Guatemala, and, of more importance, the first major tomb to be found dating from the Miraflores phase of the Preclassic period. Excavations were undertaken with labor generously supplied by the Department of Public Works, under the combined direction of Dr. Kidder and Mr. Shook, ably assisted by Sr. Gustavo Espinoza.

The tomb had been cut into the top of an existing pyramid, 13.4 m above ground level, in a series of three terraces stepping in on all four sides toward the burial chamber, a rectangular pit measuring 3.2 m north-south and 1.7 m east-west. Four large wooden posts had been set, one in each corner, to support two heavy north-south longitudinal timbers, on which were placed close together the east-west transverse beams that roofed the chamber. Prior to roofing, the burial of a most important personage took place, the body apparently laid on the floor. The position of the skeleton could not be determined because the eastern half of the floor had been cut away by the brick-factory workmen. However, the jade ornaments which must have accompanied the body were found near the center. Abundant pottery vessels and other offerings had been piled to the height of the roof around the tomb's walls. Further mortuary offerings were heaped on the roof and the terraces. The remainder of the pit was filled with mixed earth to the level of the pyramid top, and a thin adobe floor laid over the tomb area. Some slumpage occurred from settling, and perhaps from the breakage

of the vessels by the pressure of the fill, and several other floors were added to level up. Also, a small rectangular adobe platform, perhaps a shrine, was built directly above the tomb. It appears that these floors and the platform were temporary measures to permit the continuation of ceremonies dedicated to the deceased, while a completely new pyramid was being constructed to encase the one into which the tomb had been cut.

The tomb's location in the principal Miraflores structure at Kaminaljuyú, the enormous work involved in its construction, and its rich furnishings give ample evidence of the position of great honor and esteem held by the deceased. The mortuary offerings included some 300 pottery vessels; finely wrought vessels of marble, greenstone, and jade; stone mortars and pestles, several of the mortars carved in the form of toads; the carved "mushroom" stone previously mentioned; about 100 obsidian-flake lancets; one large eccentric flint; jade beads, earplugs, and pendants; shell ornaments; mica sheets; mineral paints; and objects made from armadillo shell. Perishable items were evidenced by textile, mat, and wood impressions. Among the pottery vessels were effigies, pieces decorated with painted stucco, and at least eight with covers, a feature common for certain forms in the later Esperanza phase but heretofore unknown in the Miraflores phase.

While the tomb excavation proceeded, careful watch was maintained on the digging done by the brickworkers on the other parts of the mound. We were able to determine that E-III-3 consisted of a succession of pyramidal adobe structures, facing south, built one over the other. Each adobe accretion had an elaborate frontal platform which underwent several renovations before being buried by the next pyramid. Low, rectangular platforms with postholes at each corner were found on one frontal platform; on the floor near by, severely burned rectangular depressions containing ashes and charcoal. The latter appeared to be hearths for ceremonial fires, the former to support small individual shrines of perishable material.

The entire building activity in Structure E-III-3 apparently took place during the Miraflores Phase. No evidence was seen in the fill of the latest pyramidal addition or on its surface that the mound had been used during the subsequent Classic and Postclassic periods.

Other activities of 1947-48 were as follows:

The southwestern section of Kaminaljuyú was mapped, completing the surveyed plan of the site. The principal group there consists of eight mounds arranged in an orderly manner on the four sides of a plaza. The court and area surrounding the mounds had been excavated in ancient times to a depth of 4 m from the original ground level. This left the eight units, each 4 m high, of undisturbed sterile volcanic deposits.

Five of the mounds remained unaltered thereafter, whereas the heights of three were increased in the normal manner by the addition of more material.

Several weeks were spent in Quezaltenango recording in detail the archaeological material recovered by Sr. Vitalino Robles from the ruins of El Paraiso [Chapter 22.10]. This completes the field data for the publication of the ruins of El Paraiso.

One month was devoted to the study and photographing of the various private collections in Tiquisate. Most of the specimens in these collections were found in the Tiquisate zone during the building of roads, the cutting of drainage canals, and the installation of pipe lines. The stratigraphic excavations made in 1947 [Chapter 22.10] permit the utilization of this large body of material. Its full value may be appreciated when one considers that several years of intensive work and the expenditure of a large sum of money would be required to recover a comparable amount of data. The United Fruit Company again generously provided facilities and assistance in this study.

Mr. Stanley H. Boggs, after two years as archaeologist of the Zaculeu Project, resigned in the summer of 1947. Mr. Richard Woodbury was appointed in his place. By request of Dr. Kidder, Mr. Shook spent three weeks in Zaculeu helping Mr. Woodbury to become acquainted with the work accomplished during the previous seasons. At the same time this gave Mr. Shook opportunity to improve his knowledge of Zaculeu ceramics. The pottery sequence showed that Zaculeu was founded during the Early Classic Period and was continuously occupied until the conquest by the Spaniards in A.D. 1525. Only a small amount of material has been recovered representing certain periods, especially the Late Classic. This may be due more to failure to locate structures than to lack of occupation of Zaculeu during those times.

A brief reconnaissance was made in El Salvador in the company of Mr. Boggs. The major archaeological zones of Campana San Andrés, Chalchuapa, and Cihuatán were visited, as well as many smaller sites. Cihuatán proved to be a large site strategically located on a slight elevation overlooking the broad, fertile valley of the Acelhuate River, a tributary of the Lempa. House platforms, temple pyramids, a late type ballcourt, and the wall enclosing the central plaza are well preserved. The house platforms are concentrated on the gentle slopes outside the walled area, suggesting the typical Latin American town of today, while the people live around a religious and civic administrative nucleus. Cihuatán appears to have been an important center in the Postclassic Period and may have been occupied at the time of the conquest.

A short trip to Tikal with Dr. and Mrs. E. Wyllys Andrews was made to estimate the time and equip-

ment necessary to obtain a record of the architectural remains readily available there without excavation. There exists in Tikal more exposed and well preserved architecture than in any other site known in the Department of Petén. It would require one field season to photograph and study adequately this material without undertaking more than minor excavations.

23.6.

EDWIN M. SHOOK

Guatemala Highlands

YB 48:219–224, 1949

The cutting away of Structure E-III-3, Kaminaljuyú, to obtain material for bricks continued throughout the past year. The great mound as previously reported [Chapter 23.5], is the largest individual structure of some 200 which make up the ruins on the southwest edge of Guatemala City. The salvaging of the invaluable archaeological material and data from the excavations was possible through the co-operation of Sr. Moises de León, superintendent of the government brick factory. He not only placed several laborers under our supervision, but permitted his workmen to be shifted here and there on the mound to facilitate the recording of the exposed remains.

Information was gathered on the architectural development of Structure E-III-3 from a small semicircular adobe unit about 12 m high (no. 1) through six successive major additions. The final stage (no. 7) was a massive, flat-topped, rectangular pyramid over 20 m in height and measuring 70 by 90 m at the base. Ceramic material obtained from the fill of each unit indicated that the long sequence of architectural activities took place during the Early and Middle Miraflores phases of the Preclassic Period. The lavishly stocked Tomb 1, reported in [Chapter 23.5], had been cut through the top of Structure 5. A similarly constructed and equipped tomb, no. 2, was found during the past field season. It had been dug through the top of Structure 6, the next pyramid, which completely encased Structure 5 and Tomb 1.

Tomb 2 occupied a position just west of and higher than Tomb 1, its east wall actually penetrating the upper west bench of the older tomb. Although less carefully constructed and less richly furnished, Tomb 2

provided more information because it had not been disturbed by the brick-factory workmen as had Tomb 1. Prior to the roofing of the tomb with timbers, the principal individual, a mature adult, had been laid horizontally, head to the south, on a low wooden table or platform resting on the tomb floor. The body was completely painted red and probably dressed or wrapped. Two children, about 8 years of age, had been sacrificed and placed in an extended position on the tomb floor just west of the principal body. Another skeleton, that of a young adult, lay extended, face downward, on one of the cast benches above the roof of the tomb. Over 100 pottery vessels, some containing ash and charcoal, had been placed on the surrounding benches after the timber roof was laid.

In contrast with Tomb 1, only a few pottery vessels were found on the tomb floor. Here, however, were most of the nonpottery objects: mica sheets, sting-ray tails, fossil fish teeth, stuccoed containers (possibly gourds), quartz crystals, water worn stone pebbles, basalt implements, bone spatulas and ornaments; mosaic mirrors of pyrite and of crystalline hematite, obsidian pellets and flake-blades tubular jade beads, mosaic sets, and a mask or headdress heavily incrustated with jade elements. The last was found face down off the southeast corner of the wood, platform that had supported the principal body. The decay of the platform, or a fragment of falling roof timber, may have rolled the object to the tomb floor. The backing of wood and leather, we believe, was still firm when this occurred, and the heavy jade elements remained in position until falling material settled around and covered the whole. This earth fortunately maintained the original form of the object fairly well after the backing rotted, and the recording and removal of the jade elements more or less in their original positions were possible. The headdress or mask has been reconstructed by the artists of the Archaeological Museum of Guatemala.

After Tomb 2 was roofed, additional offerings were placed on the benches and the large space was filled with earth from the roof level to the floor of Structure 6. An adobe floor then covered the entire tomb area, permitting the use of the pyramid-top again. At the same time, we think, the last great increment to E-III-3 was started. Prior to the completion of Structure 7, which added some 4 m to the total height of the mound, Tomb 2 was re-entered and partially rifled. The looters disturbed only the principal skeleton, from the pelvic region to the head; we found none of those bones in place. We did find scattered human bones and teeth in earth mixed with red paint, well above the tomb floor, apparently from the main skeleton and cast aside by the looters. The jade ear ornaments, necklace, and pendants which normally would adorn a person of such obviously high rank were entirely missing. The jade-

incrusted headdress beads lay off to the sides of the wood platform and were overlooked by the looters perhaps because they were covered by debris.

The evidence strongly suggests that only one generation (25 years or less) elapsed between tombs. The occupant Tomb 2 may have been the immediate successor of the individual buried in Tomb 1. Some striking changes had taken place in Kaminaljuyú in those few years. A higher percentage of Usulután Ware vessels was found in Tomb 2, many of them similar in shape to fine, incised red ware bowls, with everted rims and three sharply pointed nubbin feet. The latter vessels, although among the most common in Tomb 2, did not occur in Tomb 1. They apparently developed during the interim for specialized ceremonial uses, and often are found containing ashes and charcoal. As a result of the burning, the bowls' interiors frequently are blackened. Tomb 2 contained no "mud" pots or frog effigy vessels of fine red ware, as did Tomb 1, no stone vessels, mortars, or "mushroom" stones. The less care shown in the construction of Tomb 2, the fewer offerings, and the evidence of looting may indicate that the principal individual buried there had not been so successful a ruler or priest as his predecessor, or that economic conditions at the time of his death were more severe than at the beginning of his rule.

Structure E-III-3 is only one of a number of ancient structures being dismantled in Kaminaljuyú. Periodic visits to the various excavations helped to gather much information that otherwise would have been lost. Fortunately, one of principal mound groups has been set aside through the civic interest of the owner Sr. Arturo Samayoa, to be, preserved as a national monument. The National Institute of Anthropology and History has appointed a caretaker, whom we have trained, to maintain the monument and to collect archaeological material as it is excavated elsewhere in Kaminaljuyú.

Modern road construction and trenching for pipe lines led to more discoveries in the past year that amplified knowledge of the oldest known ceramic phase in the Guatemala highlands, the Las Charcas, and of the subsequent Sacatepéquez phase. Both of these pre-date the long Miraflores phase. An ancient pit, containing a rich deposit of apparently pure Las Charcas material, was found in Colonia Progreso, southeast of Mound B, Kaminaljuyú. The material, sealed by a heavy layer of obsidian flakes, included a wide range of ceramic types illustrating many specialized features. Among the latter were spouted and shoe-shaped vessels, effigy monkey heads broken from vessel walls, small solid crudely hand-modeled monkey figurines, two cylindrical and two stemmed flat seals or stamps. Also found were many burned adobe fragments bearing impressions of leaves, corncobs, and other vegetable, objects, carbonized seeds of several fruits, and

ashy remains of woven fibrous material. The Colonia Progreso find represents the first large lot of Las Charcas material recovered by a controlled excavation.

Further search along the newly constructed Roosevelt Highway west of Guatemala [Chapter 23.5] disclosed more deposits of the Sacatepéquez phase, usually in deep rectangular or circular bottle-shaped pits. The pits occur sporadically along the road from San Bartolomé Milpas Altas to Chimaltenango. Archaeological sites with mounds were located in the vicinity of the pits, but direct associations were difficult to ascertain, because the surface material collected from these sites shows that occupancy continued into later periods. The ruins, in order along the highway, are Xaraxong, Chacaya, Santa Maria Cauque, Manzanales, Los Pinos, San Roberto, Río Sumpango, Tejar, Tejarcito, Santa Fe, El Rancho, and Santa Sofia. The last six sites are in the Chimaltenango Valley; the others, in the Río Sacatepéquez Valley.

Advantage was taken of an opportunity offered by Mr. Hugh Craggs, of Guatemala City, to accompany him on an automobile trip through southeast Guatemala, Salvador, and Honduras. A brief reconnaissance was made of eastern Salvador, the coastal plain of Honduras north of the Gulf of Fonseca, and the highland valleys of Zamorano, Tegucigalpa, and Comayagua. The archaeological museums of Comayagua and Tegucigalpa and the ruins of Tenampua and other sites were visited.

Firsthand observation of the topography and climatic conditions of eastern Salvador and of southern and central Honduras directs attention to the importance of the natural intercoastal corridor running from the Pacific coast via the Río Goascoran Valley to the upper Comayagua, thence to the Ulúa Valley and north coast of Honduras. Through this natural funnel must have flowed not only aboriginal commerce, but forces affecting the cultural development of much of southern Mesoamerica. Eastern Salvador and the upper Comayagua Valley have a concentration of ancient remains showing occupancy over the known range of pre-Columbian history. It is most desirable that a study be made of the Río Goascoran drainage from the Pacific lowlands to the upper Comayagua Valley.

Shook also visited the archaeological zone of Chalchuapa, where the Salvador Government for several years has carried on intensive excavation and repair of the principal structures, under the able direction of Mr. Stanley H. Boggs.

In southeast Guatemala a record was made of the small, hitherto unreported site of San Juan Las Minas, 1 km west of Asunción Mita. The extensive, well known ruins of Asunción Mita, south of the modern town, have been noted for their excellent state of preservation, the quality of the thin-slab masonry, and the cor-

belled, arch used by the builders to roof their structures. This is the most southern site on record, where the Maya-type vault was utilized. Despite the importance of these ancient buildings, they were being destroyed to obtain stone for road construction. Shook submitted a report to the Institute of Anthropology and History which curtailed the quarrying of the site except for the main structure, already beyond saving. Strömsvik later visited Asunción Mita and obtained as full a record as possible of what remained.

In 1945 the Guatemala Government began an agricultural colonization project in the southeastern corner of the Department of Petén. Poptún, a small village near the headwaters of the Río Machaquila, was selected for the permanent site of the colony and renamed Poptún. The operation entailed intensive land clearing for agricultural experimentation, surveys, building of the physical plant, and opening of a highway to Cardenas on the Río Sarstoon. The road, to be completed in 1949, is being constructed from Poptún south through San Luis and north from Cardenas. Since 1945, reports have been received repeatedly from individuals and through the local press of archaeological discoveries made in Poptún, Cardenas, and along the highway. This past year the governor of the colony, Col. Ernesto Alvarez, invited the Institute of Anthropology and History and Carnegie Institution to visit Poptún and report on the finds. Lic. Adolfo Molina, then Director of Institute, R. E. Smith, and E. M. Shook went to Poptún in November and spent four days recording the cultural material, and mapping and photographing archaeological sites.

Five ancient sites, Los Cimientos, Hortaliza, Sabana, Poptún, and Peténsuc, were studied briefly during the visit. They lie roughly in an east-west line, north of the modern settlement, between the drainage of the San Pedro and Machaquila Rivers. The remains of Poptún are the best preserved architecturally. They undoubtedly represent what was the region's civic and religious center. There are three known groups, South, Central, and North, connected by a broad artificial causeway with a low masonry parapet on each side.

The North Group consists of five rectangular platforms of fairly well cut stone masonry on top of a leveled and terraced, limestone hill. The southern base of the hill also was terraced, but no masonry stairway connected, the lower with the upper terraces. Apparently, a pathway zigzagged up the steep hillside to the structures on top. The causeway from the South and Central Groups joined the great basal terrace of the North Group. Here a single plain stela of limestone was erected.

No evidence was found in Poptún or in the small outlying sites that the Maya here used the typical vault or even masonry buildings. All the masonry noted in

the area was for substructures, terraces, and low walls bordering courts, terraces, and causeways. The substructures were low rectangular platforms to support houses and temples constructed of perishable materials.

Poctún evidently was never a major center. It may have served the civic and religious needs of a comparatively small population scattered widely throughout the area. Although there is evidence from the cultural material of occupation from Preclassic (Chicanel) to Late Postclassic time, the period of greatest activity was during the Late Classic (Tepeu).

Engineers of several American oil companies have for the past two years been making an intensive topographical survey of the Department of Petén. They have discovered many hitherto unreported archaeological sites and caves containing ancient cultural material, and deposited their data, maps, and specimens with the Division. Dr. Barnum Brown, of the Sohio Oil Company, made important discoveries along the Río de la Pasión from the junction of the Santa Amelia to the confluence of the Río Salinas or Chixoy. He recovered quantities of petrified bones of Upper Pleistocene fauna on bars and barrier reefs along the Pasión. They had been washed out from deposits somewhere on an eastern tributary of the stream, possibly the Río Santa Amelia. One bone fragment, as yet unidentified but thought to be that of a sloth, has three sharp V-shaped cuts on the unbroken external surface. These cuts, according to Dr. Brown were made in living tissue. If the cuts were made by man, as Dr. Brown thinks, this is the first evidence found in Guatemala of man associated with now extinct fauna.

Dr. Brown also discovered an artificially built island in the Río de la Pasión, above the ruins of Seibal, and a previously unreported sculptured stela at the latter site. He collected large samples of pottery from various points along the river, including Seibal and Altar de Sacrificios. The ceramic material shows a range of occupancy in southern Petén from the Chicanel phase of the Preclassic through the Early and Late Classic periods.

Two efforts were made during the spring of 1949 to locate the conquest town of Nito, an important commercial center of the Indians. The town was conquered by Gil González in 1524 and renamed San Gil de Buena Vista. Apparently the site proved unsuitable to the Spaniards and they soon abandoned it for a new location on the Río Dulce near the sea. The Spanish name, often reduced to San Gil, as well as the Indian name Nito, continued to be applied synonymously to the new town site where, in April or May 1525, Cortés arrived after his extraordinary march overland from Mexico to Honduras. Cortés found his countrymen starving at San Gil and shortly after his arrival he moved them to Honduras. Since the abandonment in

1525, both sites, San Gil near the sea and Nito the original Indian trading town, have been unoccupied and their exact locations lost. It is of historical significance to place these sites and especially to obtain from Nito data on cultural material anchored firmly in Christian chronology.

A launch and other facilities were generously provided by the United Fruit Company through the courtesy of Mr. William Taillon and Mr. Edward Farnsworth. The latter accompanied Shook on the second expedition. Two areas were intensively investigated. The first was the south side of the Golfete, the body of water connecting Lake Izabal with the Río Dulce, which existing information suggested as the most likely area in which to find Nito. Several days were spent along this shore, penetrating the dense tropical jungle wherever possible and pushing a dugout canoe up the tributary streams. Finally an elderly native of unusual intelligence was encountered. He knew the area well, including a navigable stream, an abandoned property, and a site with mounds, all still known as San Gil. He had discovered and removed a fragmentary bronze bell from the site about 18 years ago. The bell was later seen and recorded by Shook and efforts were made to have it sent to the Guatemala Museum.

We followed the Río San Gil upstream for approximately 3 km from the Golfete. Only the first kilometer was navigable in a dugout canoe, the next 2 km having been blocked by fallen trees and by sand bars, but the entire distance would be navigable by canoe if the stream channel were cleared. At the 3 km point two shallow, swift-running branches join to form the Río San Gil. Here the land is level, fertile, and at present heavily overgrown with dense tropical rain forest. This latter condition so obscured the area that, though we searched over a wide zone, we were unable to locate the mounds where the bell had been found. The general locality, Shook nevertheless believes, must have been the site of Nito. Strong evidence for it is the survival of the name San Gil for the place, the river, and a high mountain rising immediately behind, as well as availability of a fine water supply and access by canoe to the Golfete.

The second area investigated extends about 4 km along the south bank of the Río Dulce, from its mouth opposite Livingston to the foot of the mountain range paralleling the coast. Here undoubtedly was the later settlement of San Gil de Buena Vista, where Cortés found the Spaniards. Most of the 4 km may be eliminated as unfit for settlement because of swamps and lack of fresh water. Two places were found to offer adequate facilities to sustain a small colony. One, on elevated and well drained ground 2 km southwest and upstream from Livingston, still is known as Buena Vista. An excellent spring of fresh water issues from

the base of the hills only about 50 m back from the Río Dulce. No ruins were visible, but reports from the local people tell of ancient artifacts being found when the land is cleared for corn planting. The other possible location is on a high bluff at the outlet of the Río Dulce, known today as Herreria Point. A fresh water supply from two small streams is available and there is a certain amount of cultivable land. A small preconquest Indian site (Herreria) was found overlooking the Caribbean Sea 500 m south of the Río Dulce. Broken china, crockery, and glass bottles gave evidence of occupation during Spanish colonial and modern times, but nothing definitely assignable to the early colonial period was found.

While awaiting transportation in Puerto Barrios, Shook mapped and recorded previously unreported site called San Manuel. The ruins are situated on the south bank of Río Cacao and are cut by the auto road to Santo Tomas. The principal structures are so grouped around a plaza as to form an oval, in contrast with the normal rectangular arrangement. Some 40 or more mounds, the majority low house platforms, compose the site. All are substructures built of earth. The largest structure, about 5 m in height, has its surface partially faced with water-rounded boulders. No hall court, stone sculpture, or surface pottery was found to suggest the occupation period of the site.

23.7.

EDWIN M. SHOOK

Guatemala

YB 49:197–198, 1950

A major portion of the past year has been spent in preparing for publication reports on excavations done in Guatemala since the war. Some time, however, was spent on field work as the opportunity arose. Close attention was given to the accelerated destruction of Kaminaljuyú as the modern city of Guatemala encroaches more and more on the old site. The cutting away of Structure E-III-3, as reported in [Chapters 23.5 and 23.6], exposed many more architectural features. The information was salvaged whenever possible, including that dealing with a fine broad stairway belonging to one of the earlier structures in the great mound. Near by, several other mounds were removed completely by the Guatemala Government, the mate-

rial from them being utilized for the making of bricks. Before their complete destruction, a large sample of pottery and artifacts, as well as charcoal samples for dating purposes, was obtained. Two of the mounds, E-II-3 and E-III-1, proved to have been built during Providencia times, the oldest Miraflores subphase. Another huge structure, D-III-10, also dating from this early period, is being destroyed. Information was obtained on the adobe architecture, and from its fill came the only example of wood, that of a large main post, ever recovered from Kaminaljuyú.

Structure D-III-13, the cutting away of which has been going on for several years, proved to be of considerable interest. The brickyard workmen discovered a minor grave, near the mound's base on the west side, which Shook excavated. Several stuccoed and painted vessels, minor burial furniture, and a large sample of charcoal from fires burned contemporaneously with the interment were recovered. The pottery pertained to the Early Classic period, probably somewhat earlier than the known part of the Esperanza phase. The discovery of this grave, a plain stela erected above it, and a part of a red-painted adobe structure with its stairway beneath still another stairway of stone plastered with adobe resulted in our requesting Drs. Heinrich Berlin and Joel Canby, of the Institute of Anthropology and History of Guatemala, to undertake minor excavations. They began at the top of the mound, working out a number of summit platforms of successive architectural units much like those found by A. V. Kidder in Mounds A and B. Their excavations brought to light more caches of incensarios and many pottery vessels, amplifying knowledge of the early Esperanza phase in Kaminaljuyú and proving the existence of considerable architectural activity at the site between the Miraflores phase and the construction of Mounds A and B. Three large charcoal samples from different architectural stages in Structure D-III-13 will permit, it is hoped, the accurate dating of this important new material.

In the vicinity of Kaminaljuyú, Shook discovered and excavated two more pits containing Las Charcas material, representing the most ancient cultural horizon now known in highland Guatemala. Drs. Foshag and de Borhegyi located, and kindly informed Shook of, another series of ancient pits about 1 km south of the main site, many of them filled with Las Charcas phase rubbish. One pit excavated contained the richest lot of Las Charcas material, and the only burial, yet recovered. On the pit's floor lay extended, face up, the skeleton of a young adult without ornaments or formal grave furniture. Over the body had been dumped an incredibly rich midden. This consisted of dark brown soil; ashes; carbonized wood, corncobs, and fruit seeds; animal bones; disarticulated human bones; fragments of stone metates, manos, polishers, and

simple sculptures, bone tools, pottery vessels, figurines, whistles, incensarios, and a large hollow cylindrical seal. No pottery vessel was unbroken, and sherds of the same pot were scattered over the 3 m diameter of the pit from the floor to 1 m above. Many of the restorable vessels showed considerable wear, a further indication that new pots had not been broken ceremonially and thrown into the pit. The quality of pottery and artifacts and the decorative techniques employed show strikingly that even though this was a very ancient cultural horizon, it was in no sense primitive.

Further exploration along the Roosevelt highway west of Guatemala City in the Department of Sacatepéquez disclosed more sites and deposits of Sacatepéquez phase material, which we believe to be younger than the Las Charcas and older than the Miraflores phase. Several new sites were discovered in the Chimaltenango and Antigua valleys. Privately owned archaeological collections in Antigua were photographed and fully recorded. These collections often contain excellent complete specimens which could not be found by controlled excavation without considerable expenditure of time and funds.

The personnel of the United Fruit Company constantly informs the Division of discoveries made on the Pacific coastal plain at Tiquisate, Department of Escuintla. Kidder and Shook, in August 1949, spent four days in Tiquisate recording and making minor excavations at a large, hitherto unreported archaeological site named by them Sin Cabezas. Four beautifully sculptured human figures seated on pedestals were aligned in front of acropolis-like structure at the southern end of the main plaza. All the statues lacked heads, and, although the heads were diligently searched for in the immediate vicinity, none was recovered. It seemed evident that they had been broken off and removed from the site, possibly in ancient times by invaders. The ceramic material excavated indicated that the ruins had been occupied principally in the Late Classic period.

Shook attended the twenty-ninth International Congress of Americanists, held in New York in September 1949. Opportunity taken during this trip to study collections from Mesoamerica at Tulane University, the University of Pennsylvania, and the American Museum of Natural History. On his return trip to Guatemala a few days were devoted to studying the site of Tlatilco, on the outskirts of Mexico City, and the rich collection of material recovered from that site. An attempt to relate this highly developed culture to the sequence established in the southern highlands of Guatemala was not too successful. At the moment it appears to fit best in late Miraflores times, about the Arenal subphase. It should be pointed out, however, that Shook was unable to identify a single specimen in

the Tlatilco collection which may have been traded from Guatemala nor has he been able to find a Tlatilco trade piece in Guatemala.

Strömsvik and Shook went to Yucatán for 10 days in November to assist Mr. Morris Jones in establishing a camp in Telchaquillo and beginning a detailed survey map of the ruins of Mayapán.

23.8.

EDWIN M. SHOOK

Guatemala

YB 50:240–244, 1951

Knowledge of man's cultural development in Mesoamerica before the Classic period was augmented this year by a discovery made in Kaminaljuyú on the outskirts of Guatemala City, when a workman began removing sod from a grass-covered mound, C-III-6, located on privately owned property, Quinta Samayoa. This property, formerly known as Quinta Arevalo, lies entirely within the archaeological site of Kaminaljuyú, and the major concentration of ancient mounds is within its boundaries. The workman, while chopping out squares of sod from the top of Mound C-III-6, struck a stone with his hoe. Being familiar with the local terrain, where no natural rock exists, he was curious and began clearing the stone. It proved to be the plain shaft of a pedestal sculpture which had been set vertically into the top floor of the mound. The excavation of this stone brought to light another, some 50–60 cm below the surface, which proved to be an excellently preserved carved stela of columnar basalt. The property owner, Sr. Arturo Samayoa, had the stela removed to his house for safekeeping and notified the Institute of Anthropology and History of the discovery. Shook, on request of the Institute, investigated the report and recommended minor excavations where the monument had been found. The purpose was to observe, if possible, its association with pottery and other cultural remains.

Several weeks were spent excavating Mound C-III-6. The sculptured stela formed part of an incredibly rich cache placed in a large, roughly rectangular intrusive pit. The pit had been cut through the structure's top floor to a depth of 1.4 m and floored with an enormous stone slab. Around the slab had been placed three plain basalt columns, the stela, and two pedestal sculptures. The last extended above the mound's floor

level and had been broken off and removed, probably in ancient times leaving only their plain pedestals buried in the mound fill. Also found in the cache were over 70 pottery vessels, a bird (?) skull containing a necklace of 290 emerald-green jade beads and pendants, a jade pendant carved in what Shook believes to be the so-called Olmec or La Venta style, and 23 small jade beads and mosaic elements. Ceremonial fires had been burned around the base of the pit, leaving quantities of ash and of charcoal, a sample of which was obtained for carbon 14 analysis. Among the ashes were scattered fragments of the pottery vessels, which had been broken ceremonially. Subsequently the pit was filled and the area resurfaced with an adobe floor, and presumably the structure continued to serve its original purpose.

Excavations were made below the intrusive pit through undisturbed mound fill to a sterile level. A few potsherds were recovered, and all that could be identified belong to the Las Charcas phase, the most ancient known in the Guatemala highlands. The cache, however, being later than the construction of the mound, contained Early Sacatepéquez phase pottery believed to represent a transitional stage between Las Charcas and Sacatepéquez.

The excavations in Mound C-III-6 prove that architecture of a permanent nature, serving public and ceremonial functions, began in Kaminaljuyú at a much earlier date than was hitherto believed. Monumental stone sculpture, jade cutting, carving, and polishing show a well developed technology. The jade pendant carved in the form of a human figure was evidently an import. If the specimen is in fact a product of Olmec-La Venta art, it represents the earliest example yet found associated with archaeological material recovered under controlled excavation.

Two nearby mounds show a type of construction similar to that of C-III-6. A ceramic sample from the fill of one, C-III-10, consists mostly of Las Charcas wares with a few examples of Early Sacatepéquez type.

During the year, wood or charcoal samples were obtained for carbon 14 analysis from several locations at the ruins of Kaminaljuyú and Tikal in Guatemala, and at Tulum on the east coast of Quintana Roo, Mexico. A total of 30 specimens have been collected from archaeological sites throughout the Maya area, ranging in time from the oldest levels now recognized to within a century of the Spanish conquest. These samples are in the Department's office in Cambridge, Massachusetts, awaiting analysis.

24.0. SITES NEAR LAKE PETÉN (TAYASAL, POLOL, CHAKANTÚN, TOPOXTÉ)

At the time of the Spanish conquest Tayasal was the most prominent site in the Petén lowlands of northern Guatemala. Most scholars locate Tayasal on the shores of Late Petén Itzá, most likely obscured archaeologically by the modern capital of Flores. Historical evidence suggests that Tayasal was founded on the edge of Lake Petén Itzá by transplants from Chichén Itzá in northern Yucatán. These Itzá Maya, under the control of the Canek lineage, maintained a vestigial overland trade network through the central and southern lowlands. In 1524–25 an expedition to Honduras, led by Hernán Cortés, passed through the Maya lowlands and the settlement at Tayasal was discovered. In 1618 Fr. Fuensalida and Fr. Orbita visited the site, and in 1697, Tayasal, the last capital of the independent Maya was captured and destroyed by the forces of Martín de Ursua. The approach of a new katun cycle that augured momentous changes may have hastened the destruction of Tayasal.

24.1.

CARL E. GUTHE

Report on Tayasal

YB 20:364–368, 1921

Dr. Guthe sailed from New Orleans on February 11, 1921. During the latter part of the month a week was spent in excavating a small mound within the borders of British Honduras, at a clearing called New Boston, 4 miles [6.4 km] east of Baker, a village on the banks of the Belize River. After returning to Belize to meet Mr. Gates, Dr. Guthe left on March 7, met the rest of the expedition in El Cayo, British Honduras, and proceeded at once, with Mr. Ricketson, to Flores, Petén, arriving there on March 18. The first two weeks were spent in making a transit survey of the principal plazas of Tayasal. Actual excavation began April 5 and continued until May 21. Dr. Guthe left Flores on May 23, arriving in the United States on June 9.

The excavations at New Boston were made possible through the kind offices of Dr. T. Gann, of Belize, and the officials of the Belize Estate and Produce Company, to whom the land upon which the mounds are situated belongs. The purposes of this excavation were two-fold: to obtain some data upon the construction of

mounds in this area and to secure a collection almost entirely of potsherds from this district.

A mound which consisted almost entirely of large and small stones, with very little earth, was trenched from one side to the center. Two walls of dressed stone, one running at right angles to the other, were uncovered. Neither extended to the surface. The foundation course in both cases was composed of large flat stones which projected beyond the face of the wall proper. A small but representative collection of sherds was secured. The mound also yielded a few fragmentary human bones, a serpentine bead, and some partly finished flint objects. Since flint outcrops are numerous in this district, it is safe to assume that flint-working played an important part in the economic life of the builders of these mounds.

Upon reaching Flores, Dr. Guthe met with instant and hearty cooperation on the part of the government officials under Dr. José Prado Romaná, the governor of Petén, and of Dr. Robert Boburg, a resident Englishman. Unusual labor conditions and the strange class of work required caused some trouble at the beginning, which was, however, soon regulated.

The early Spanish writers state that the Itzá left their home, Chichén Itzá in northern Yucatán, about the year 1450 and went south, founding a city they called Tayasal, upon a large island in the lake of Petén Itzá. The purpose of the present expedition was to verify as far as possible the historical and geographical information contained in the early reports of this site (Means 1917), to secure an accurate idea of the plan and extent of the ruins, and to do what preliminary excavations seemed advisable.

Recent archaeological investigators in this country have ascertained that this city is now upon a large peninsula which juts into the lake from the east. The present capital of Petén, the little village of Flores, is situated upon a small island within a quarter of a mile [0.4 km] of the shores of this peninsula. Through conversations with inhabitants of Flores who knew the surrounding country, and by means of personal observations of the topography and present lake of Petén Itzá, it was possible to explain and clarify, in a most gratifying manner, many of the statements of the early Spanish writers which were obscure or seemed to be actually contradictory. Current place-names were secured for some of the spots mentioned in the early accounts, and the itineraries of the seventeenth century explorers were worked out with a fair degree of accuracy. Copies of three of the early maps of the district were interpreted satisfactorily by a study of the region at first hand.

During Dr. Morley's visit to Flores, careful measurements were made to determine the probable amount of subsidence in the water-level of the lake

since the end of the seventeenth century, which made of the then island a promontory. A rock outcrop near the plaza of Flores, with a design incised upon it, is 45 feet [13.7 m] above the present water-level. A very distinct line of demarcation on the peninsula itself, between the low jungle growth of the lake shore and the grasslands which cover the ruins proper, is approximately 40 feet [12.2 m] above the present water level. From this evidence and other corroborative data, it seems probable that 225 years ago the water level was between 40 to 45 feet [12.2–13.7 m] higher than at present. There is some contradictory evidence, such as finding potsherds below this former water level, but the general mass of evidence, including that in the early maps, is overwhelmingly in favor of the figures given.

The civic and religious center of Tayasal, as marked by the larger mounds, occupies the western and highest part of the former island, covering an area about 2 km long, by 0.8 km wide. The topography is fairly rugged with numerous outcrops of limestone, causing many and sudden irregularities in the surface. The mounds were placed with due regard to these irregularities, and in some case use was probably made of the natural knolls in their construction. The eastern part of this civic and religious center is lower than the western part, and covered with a dense growth of high underbrush. At the eastern end stands a huge pyramid which commands the entire surrounding country. Another large pyramid marks the western end, which practically coincides with the end of the peninsula itself. The western part is now covered with high grass, which permits the mounds to stand out clearly. In addition to the center of the city, there are, of course, the more outlying districts. Smaller mounds are said to occur as far as 10 km east of the western end of the peninsula.

The highest part of the peninsula, about 0.75 km east of the end of the promontory, is occupied by a well-defined group of mounds surrounding four principal and four subsidiary plazas. A careful transit survey of this group occupied the first two weeks of the work (Fig. 24.1.1). The four principal plazas are arranged in line from east to west, each being at a higher level than the one to the east of it (cross-section at top of Fig. 24.1.1). The western and highest plaza is the summit of a large pyramid, like an acropolis, which is probably partly natural and partly artificial. The four secondary plazas are arranged around the larger ones in a manner implying consideration of the topography. This group probably marks the very center of the former city's activities. It occupies the very highest part of the peninsula; it is the most closely coordinated group of the city; and within it were found the two hieroglyphic monuments. At the very beginning of the survey, the stub of a stela with traces of hieroglyphs upon it was found approximately in the center of the

second highest of the four larger plazas.

Excavations were begun in the plaza in which this stela was found, by uncovering a small, low mound in the plaza itself, just south of the monument and apparently associated with it. When uncovered it proved to be a small square building upon a low platform, with only the foundations of the walls remaining. A space resembling a doorway was left in the middle of each side of these foundations. The masonry was partly of dressed and partly of rough stone. The walls themselves were probably similar to those made in the country today, of vertical saplings lashed to horizontal ones and then completely covered with mud or mortar. Two fragments of a lintel were found, one on the mound itself, the other about halfway between the mound and the stela, which Dr. Morley assembled and deciphered as 12.5.9.0.0, 11 Ahau 18 Mac (1467 A.D.). During the excavations here six burials, all fully flexed and entirely without furniture, were exposed.

The eastern end of the long mound on the southern side of this same plaza was also cleared; this mound proved to be a terraced substructure, the terraces varied in width, with the walls between differing in heights to an even greater extent. The masonry was not the fine stonework of northern Yucatán, but simply irregular stones, laid in very uneven courses and smoothed over with liberal applications of mortar and mud. Only the lowest wall was composed of dressed stone. These floors, on the other hand, were very fine indeed, presenting a surface nearly as smooth as a cement floor, with a foundation of broken stone several inches thick. On one terrace, at the outer edge, the floor had been raised about 2 cm, just enough to prevent the water from a torrential rain running over the side of the terrace and to guide it to a probable outlet. The floors ran underneath the walls, showing clearly that the walls were built after the floors were laid. No trace of a building could be found on the top, unless a few scattered flat stones were the remains of a foundation for a house of wattle and daub. In one section of this uppermost floor there was a distinct depression, where the floor appeared to have sagged because of some heavy weight, such as a wall, resting upon it.

Figure 24.1.1. Tayasal, map and cross-section of principal group of mounds and plazas at ancient Itzá capital. The section shown was probably the civic and religious center of the city.

A trench was run into the pyramid on the eastern side of the same plaza. The floor of the plaza itself, finished like the other floors, was uncovered, and also the very much ruined face of the pyramid. In this trench, as well as in all others, the stratification was studied carefully in order to ascertain the manner of disintegration of the mounds.

The fourth and last mound on which excavations were undertaken was the small one just south of the main group around this second highest plaza. This mound proved to be a small square building, 3.8 m on a side, set upon a low platform, 30 cm in height, which made a terrace a meter wide on all four sides of the building. On the western side of the building a steep stairway of eight steps led to the top, which was about 2 m above the platform. The walls of the building were of unfinished stones, but those of the platform consisted of well-dressed limestone. The interior of the building had been completely filled. Excavations in the center of the mound disclosed, at a depth of 3.5 m below the top of the building, a tomb of large, rough, flat limestone slabs leaning against one another to form a rude vault. In this tomb was the skeleton of some important personage, laid on its back at full length, with the head towards the north. With the burial were found five unbroken pottery vessels, an obsidian knife, and a necklace composed of 18 spherical beads of serpentine and jade, and five beads of clay and bone. Although the vessels were somewhat encrusted with lime, it was possible to obtain the designs, in

colors, of four of the 5. One, cylindrical in shape, was fluted.

The dearth of smaller objects was very noticeable. In the course of the entire excavations, not a single bone implement was found and less than a dozen stone tools appeared, but potsherds were very common indeed. A large collection was made, showing examples of all of the many variations in shapes and wares. In accordance with the permit granted by the government of Guatemala, the objects found in the tomb were deposited with the local authorities at Flores.

While excavating for a large cistern near the plaza of Flores, the government exposed several floors, many potsherds, and at least one grave. From this work two complete vessels were saved.

The interest shown by the inhabitants of Flores towards the end of the work was extremely gratifying, in view of the fact that at the beginning there was an atmosphere of tacit disapproval. On Sundays especially, a great many groups climbed the steep path from the lakeshore to inspect the work. The governor and his staff, all of whom had evinced a keen interest from the very beginning of the work, visited the excavations many times. On the eve of departure, Dr. Guthe was informed that the government would install a glass case in the public library in order to exhibit the collection, would place a guard at the excavations to protect the walls and mounds from vandalism, and also place a roof over the tomb to protect it from the weather.

24.2.

CARL E. GUTHE

Report [on Tayasal]

YB 21:318–319, 1922

Through the cordial support of General Isidro Valdez, who was governor of the Department of Petén when Dr. Guthe arrived, it was possible to begin work at Tayasal with 12 laborers on February 20. Don Bernard Burmester, the government interventor, by his interest and cooperation, also did much to facilitate the progress of the excavations. The entire season was devoted to a study of the construction of the long mound, the eastern end of which had been cleared during the previous season [Chapter 24.1]. During the course of the work six trenches were run, four on the northern or plaza side of the mound, and two on the southern side. The eastern and western ends of the

structure were definitely located. Toward the eastern end a trench was dug entirely through the mound, exposing a complete cross-section and disclosing, under the late construction, the remains of an earlier, building of the Old Empire. This earlier building was placed directly upon the rock of the peninsula, which at this point slopes rather abruptly from south to north.

The excavations this season disclosed that this structure consisted of a platform raised about 1.5 m above the plaza level, with two stairways built into the wall. Upon this platform there probably was an early building which was later razed to within one course of the platform, over which was placed a second platform, with a bench at the southern side.

The city of which this early structure formed a part was probably abandoned early in the seventh century A.D., that is, the period of abandonment of the Old Empire Petén sites. For at least seven and possibly eight centuries this city was uninhabited. During this time a thick deposit of earth, and stone accumulated south of the bench. Why no traces of a similar deposit north of the bench are found in this part of the mound is a mystery.

The settlers of the New Empire raised a high terraced substructure on this site, the retaining walls of which were built upon the ruins of the old building.

The unusually thin layer of debris upon the upper floor of this mound and the almost, total absence of large stones lead to the conclusion that the building itself was of wood and, palm-leaf thatch. At the western end, however, a fragment of a dressed stone wall was found at the northern edge of this upper floor.

Just to the south of the mound a skeleton was found. The individual had been buried in a flexed posture, on his back, with the shoulder-girdle considerably above the pelvis. This burial should be associated with the later period, for it rested upon the early floor, less than a meter below the upper or late floor. No furniture was found with it. No trace of a skull, teeth, or of the atlas and axis could be found. It is assumed that the individual was decapitated before burial, a procedure which Villagutierre states existed at Tayasal.

24.3.

J. O. KILMARTIN

Report on the Topographic Survey of Lake Petén

YB 22:272–273, 1923

The object of the topographic survey of the Lake Petén region was to ascertain whether or not the peninsulas of San Benito, Candalaria, and Tayasal were islands, as described by the different Spanish conquerors and padres at the time of their *entradas*, between 1525–1697, and which was the Petén Grande, or Island Capital of the Petén Itz'ás, and what rise of water would be necessary to convert these present peninsulas into islands.

On the peninsula of San Benito a trail leads from the village of San Benito at the point, across the mountains to San Juan de Dios, La Libertad, and other villages. Only one place was found along it (at the trail-forks and enclosed by the 490 foot [149.4 m] contour that might have been an island, and this certainly was not so at the time of Father Avendaño's visit to Tayasal in 1697. For about a mile [1.6 km] back from the lake shore the topography is fairly regular, that is, it is not broken up by small drains. This section was an old lake bed at one time. In front of the cemetery in San Benito is a small saddle, elevation 425 [129.5 m], and just to the north, extending along the peninsula, is a small knoll enclosed by the 430 foot [131.1 m] contour, but this is not to be considered.

While traversing the trail to Picú west of San Benito, a good view could be obtained of Candalaria peninsula, and what might be the lowest place appeared to be about a mile [1.6 km] back from the extreme end of the peninsula. A trail was cut into it and elevation established. Ruins were found scattered throughout this area; practically all just above the 460 foot [140.2 m] contour. The trail from San Geronimo Bay to Picú was next traversed and nothing was found tending to prove that Candalaria peninsula was ever an island.

The third, and most important peninsula under consideration is that of Tayasal, which many have thought to be the island capital of the Petén Itz'ás. After traversing the trail to Pitchallin, a line of levels was carried south to Naranjal, along an old trail which passes through a low gap on the 560 foot [170.7 m] contour, then dropping into a *bajo* (low ground), elevation 520 [158.5 m], and then into the drainage of Lake Eckixil, which is west. At Naranjal the line continued in a southwesterly direction across the foothills and on to El Yex. From El Yex the line continues to San Benito, thus completing a circuit around the entire area

involved. From Playa Trapiche a trail follows east along the peninsula of Tayasal. At the road-forks, elevation 620 [189 m], one trail continues to Sonoti and thence to Playa Puxtial, while the other continues south and east across the divide between Lake Petén and Lake Peténxel to the intersection of the trail from El Yex to San Benito.

From a point along the trail from Sonoti to Playa Puxtial a trail was cut east to the saddle on the Pitchallin-Naranjal line. No lower place than that, previously discovered, that is, 565 [172.2 m], was found, and the elevation checked favorably with the one before, which is one of the proofs that Tayasal was not an island. In the village of Flores and just below the plaza on its north side, certain glyphs are inscribed on a rock ledge, exactly 50 feet [15.2 m] above the lake-level and it is likely that these were somewhere close to water-level a few hundred years ago.

Lake Petén contains 10 islands, of which only two, Flores and Lepet, are inhabited; the remainder are of no great importance, as they show no evidences of ruins or of having been inhabited at any time. Indeed, all except Santa Barbara, Flores, Hospital Island, and the last island to the east of Flores are of recent origin, and even Lepet may also be included in this list.

To the east of Flores and Lake Petén are two large and two small lakes, the small lakes being at no time connected with the larger ones. Lake Peténxel is 13 feet [4 m] above Lake Petén, Lake Eckixil is 18 feet [5.5 m] above Lake Peténxel and 31 feet [9.5 m] above Lake Petén, and a 20 foot [6.1 m] rise of water in Lake Eckixil would connect all of these lakes.

In Lake Eckixil are two small islands; on the island to the west are ruins of perhaps one house, just above the 460 foot [140.2 m] contour. These ruins are of the same type found elsewhere throughout this region. Residents report that the water rises but little during the rainy season.

The Savana de Sonoti has many ruins similar to those on the western end of Tayasal, and two tombs found there appear to be of the same type as the one excavated by Dr. Guthe at Tayasal in 1922. Just west of the intersection of the trail to Sonoti and San Benito is a saddle 15 feet [4.6 m] lower than the one between Pitchallin and Naranjal; this also would tend to prove that Tayasal was never an island.

In drawing conclusions, we must, first of all, consider the hieroglyphs in Flores, elevation 50 feet [15.2 m] above lake-level. It is certain that these were not inscribed under water, and therefore in order to convert Tayasal into an island we must look for a saddle with an elevation that compares with this.

On Candalaria peninsula 65 feet [19.8 m] of water would be necessary to convert small knolls shown into islands, but this would obliterate the ruins. From this

we can readily see what effect 150 and 165 feet [45.7–50.3 m] of water, would have on these places.

It is hoped that the foregoing, facts, with the aid of the topographic map obtained, clearly prove that the present peninsulas of San Benito, Candalaria, and Tayasal were not islands as described by Father Aven-
daño in his sketch of Lake Petén in 1697. It is most likely that the present Tayasal was the capital city of the Itzás, but certainly it was not an island, and the padres were either wrong in their descriptions of it, or in their interpretation the Maya language.

24.4.

CYRUS L. LUNDELL

Sites near Lake Petén

YB 32:96–97, 1933

While engaged in botanical studies in the savanna region near Lake Petén, Mr. Lundell, who in 1931 discovered the city of Calakmul, found several new archaeological sites, the largest of which lies in heavy forest on the border of the savanna 5 miles [8.1 km] west of La Libertad, near the small settlement of Polol.

The Polol ruins consist of a central group of mounds covering approximately half a mile square [1.3 sq km]. This area was thoroughly explored and mapped. There are no standing buildings. The main plaza is bounded on the south by a great terraced pyramid bearing fallen temple structures. Its dimensions are: base, 318 by 390 feet [96.9 m by 118.9 m]; summit platform, 100 by 105 feet [30.5 by 32 m]; height (mea-

sured up the very steep slope), 170 feet [51.8 m]. In the plaza are 15 stelae, of which at least six are sculptured. All save one have fallen and broken. The largest (no. 10) is 7 feet 5 inches [2.3 m] wide, 2 feet 9 inches [0.8 m] thick, and almost 12 feet [3.7 m] long. It bears glyphs on the two sides, a large human figure on the face. Another (no. 3) has glyphs on sides and back, a figure on the face. From Mr. Lundell's photographs and drawings, Dr. Morley has deciphered Initial Series dates which indicate that Polol was occupied during the Great Period of the Old Empire, at least from 9.15.0.0.0 (Stela 0) to 9.18.0.0.90 (Stela 1).

The second site was found in open country 5 miles [8.1 km] south of La Libertad, south and east of the aviation field in the San Francisco, Santa Teresa, and Chica savannas. Exploration revealed numerous low mounds, terraces, stone paved courts, stone foundations and floors of round and rectangular structures extending over an area about 2 miles [3.2 km] long by a mile [1.6 km] wide. There are apparently no stelae. Mr. Lundell named the ruins Chakantún (*chakan*, savanna; *tun*, stone).

At the ruins of Tayasal on the shores of Lake Petén (YB 20 and 21) there was discovered, on the plastered surface of a terrace partially cleared by native lime-burners, a very interesting series of non-realistic pictographs: whorls, crosses, and meandering lines.

During a delay on the outward trip, explorations were made among the ruins on the islands at the west end of Lake Yaxhá. On the island of Topoxté, previously investigated by Maler, eight stelae and three altars were encountered. Of these, Stela 1 and 2 are sculptured. The most interesting structure on the island is a well-preserved terraced pyramid on the summit of which there stands a columned temple. Two adjacent islands were visited and, on a third, two additional sculptured and inscribed stelae were found. These, designated Stela 9 and 10, have not hitherto been reported. The ruins of Topoxté were mapped and the stelae on both islands were photographed.

25.0. LA MURALLA

La Muralla is one of several major sites in the Mirador basin in the northeastern Petén region of northern Guatemala seemingly abandoned by the beginning of the Early Classic period (250–550 AD). Although building construction ceased and goods were no longer being imported, Late Classic period codex-style pottery was still being manufactured here and at other sites in the region.

25.1.

MONROE AMSDEN

Report on the Muralla Expedition

YB 26:266–289, 1927

The ruins of La Muralla lie about 50 miles [80.5 km] northwest of Uaxactún and 10 or 15 miles [16–24 km]

south of the Campeche border, in a section of the Petén forest that is almost completely unexplored. They were discovered by a Negro chiclero during the rainy season of 1925, and were reported by him to Captain Vans Agnew of the P. W. Shufeldt Company, who, accompanied by Enrique Shufeldt, visited the ruin in the autumn of the following year. They remained only long enough to fell a section of the bush on the north side of the decorated wall, from which the site takes its name, and to make various sketches. With the exception of a few chicleiros from a nearby camp, these were the only persons, so far as is known, who had seen the place previously or had even known of its existence.

Water in this region is quite scarce, and the presence of numerous bajos makes exploration an arduous task, even under the most favorable circumstances. The fact that during the three and a half days' trip from Uaxactún to La Muralla, the Institution's Expedition met not a single person on the road, nor passed a single inhabited place, is significant of the uninhabited condition of this part of the Petén region. Indeed

there are no permanent settlements, the temporary camps of the *chicleros* being the only communities of any kind, and during part of the year even these are abandoned. In view of such conditions, unless systematic exploration is undertaken, discovery of other ruins may be delayed for years.

This group of ruins, of which the wall is the only feature of extraordinary interest, covers an area of perhaps half a square mile [1.3 sq km]. On the south they extend to the edge of a natural terrace beyond which stretches an extensive *bajo*. This seems to run west for several miles, while east of the city it turns within a short distance and continues north. The sloping ground forms a large, rather low promontory, the city standing upon its highest point.

Mr. Amsden, accompanied by Captain Vans Agnew, reached La Muralla on February 28, and the first work, after establishing camp on a terrace near the southern base of the wall, below which there is a very good aguada, was to fell part of the bush in the plaza, upon one side of which the wall stands, and to build a scaffold of poles from which to take photographs.

The site consists of a series of long, low mounds, enclosing small plazas with here and there a solitary pyramid, of which the highest rises more than 20 feet above the ground level. All architectural details excepting the wall have disappeared. No stelae or carved stones were found. Like all untouched Old Empire cities, La Muralla lies buried in dense bush which has rendered it utterly devoid of any distinguishing features, except in contour.

Whether the wall served originally as a roof-comb or was built for some other purpose can not be determined without excavation. Its size (58 feet [17.7 m] long, 6 feet [1.8 m] high, and 5.5 feet [1.7 m] thick at the base) would apparently indicate that it was a roof-comb, were it not for the fact that the mound upon which it stands is no higher than the wall itself, which would make the floors of the rooms, if it were a roof-comb, at or near the level of the floor of the plaza. Since the mounds below the wall is very little wider than the thickness of the wall and of even width throughout its length, it is difficult to see how it can contain rooms. However, the superficial evidence is inconclusive either way.

In construction, the wall is apparently of compact rubble, faced with masonry and plastered with a coating of stucco. It is pierced vertically by openings 5 or 6 inches [12.7–15.2 cm] in width, which divide it into nine independent blocks of equal size. These are bound

together by three horizontal layers of stone about 6 inches [15.2 cm] in thickness, cornices, which project slightly from the face of the wall, dividing each face into 27 separate panels and the ends into three panels, each course or horizontal series of panels being narrower than the one below it. Vestiges of a fourth course can be seen at the top, but it has been badly wrecked by the growth of vegetation.

Of these four horizontal zones of decoration, the next to bottom probably bore figures in low relief on alternate panels, the intermediate one having instead single figures in full relief, larger than life size, seated cross-legged upon the projecting cornice and tenoned to the wall for support. The two figures on opposite sides of the second block from the east have more elaborate headdresses of feathers which fall over the shoulders and seemingly terminate in conventionalized serpents, or similar figures, in the panels below them. Against the fourth panel from the left on the north side, in the next to bottom row, sits a more modestly garbed figure in a lifelike attitude. In the third is a group in low relief composed of a man, arms bound with a rope, kneeling in a posture of servility while a second figure holding the rope is kicking him.

Another scene of violence is depicted in the third panel from the bottom in the first block. Here, a human figure lies stretched on his back with his legs dangling over the edge of a low bench. Seated at his head, a second human figure appears ready to slit his throat or tear open his breast in sacrifice. The scene in the panel directly below is more felicitous. Here a gaunt simian figure advances on tiptoe with his long arms outstretched toward another, facing it. The second figure has an abnormally distended abdomen, and possibly represents a pregnant female. Parts of other figures adhere precariously to the surface of the wall; but, excepting a highly conventionalized serpent at the northeast corner, they are mostly fragmentary and lack the interest of those described.

Mutilated as they are (the face of every human figure is gone), and even though covered with a dark lichenous coat, a graceful precision of execution is plainly seen in all, giving an appearance of beauty and of unusual artistic merit. Before decay and the forces of nature began their work of destruction, and painted as it must have been in brilliant colors, this wall must have presented a scene of barbaric splendor, of which any city, Maya or modern, might well have been proud.

26.0. PIEDRAS NEGRAS

Piedras Negras seems to have been an independent city-state for most of the Classic Period, although sometimes in alliance with other states of the region and perhaps paying tribute to others at times. It had an alliance with Yaxchilán, located some 40 km up river. Ceramics show the site was occupied from the mid-seventh century BC to 850 A.D. Its most impressive period of sculpture and architecture dated from about 608–810 AD, although there is some evidence that Piedras Negras was already a city of some importance earlier. The artistry of the sculpture of the Late Classic period at Piedras Negras is considered particularly fine. Before the site was abandoned, some monuments were deliberately damaged, including images and glyphs of rulers defaced, but images and glyphs of deities left intact, suggesting a revolt or conquest by people literate in Maya writing. The site was first explored, mapped, and its monuments photographed by Teobert Maler at the end of the nineteenth century. An archeological project at Piedras Negras was conducted by the University of Pennsylvania from 1931 to 1939. Further archeological work here was conducted from 1997 to 1999 by the Instituto de Antropología e Historia de

Guatemala (IDAEH) and Brigham Young University. Tatiana Proskouriakoff was the first to decipher the names and dates of a Maya dynasty from her work with the monuments at this site. By her request, Proskouriakoff was buried here after her death. In 2002 the World Monuments Fund financed the conservation of Piedras Negras. It is today within Guatemala's Selva Lacandona National Park.

26.1.

SYLVANUS G. MORLEY

*Report on the Piedras Negras Expedition*YB 28:327–328, 1929

On May 5, Dr. Morley left Chichén Itzá for the Old Empire center of Piedras Negras in the extreme north-

western corner of the Department of Petén, Guatemala. The journey was made by sailboat with auxiliary motor from Campeche to Ciudad del Carmen, thence up the Usumacinta River to Tenosique, at the head of navigation, and thence by mule train, 40 miles [64.4 km] south to the ruins, which are located on the east bank of the river in Guatemala.

Before publishing on the inscriptions at this site, it appeared advisable to subject them to further examination to clarify moot points, as well as to search for additional monuments, which might perhaps fill some of the few, remaining lacunae in the chronologic sequence of the monuments there.

Dr. Morley was at Piedras Negras from May 5 to May 12 and found four new Initial Series and one New Period Ending. Through the application of the Teeple formula for Glyphs C and D, of the Supplementary Series, it was, possible to correct an earlier reading of the Initial Series on Stela 23. The contemporaneous date of Altar 1 was also probably determined. The new decipherments are given below:

Table 26.1.1. Calendrical Decipherments, Piedras Negras.

<i>Monument</i>	<i>Maya Date</i>	<i>Christian Era</i>	<i>Kind of Date</i>
Stela 15	9.17.15.0.0	527 AD	Initial Series
Stela 33	9.10.10.0.0	383 AD	Initial Series
Altar 3	9.19.0.0.0	551 AD	Initial Series
Altar 4	9.18.0.0.0	531 AD	Initial Series
Stela 18	9.17.5.0.0	517 AD	Period Ending
Stela 23	9.14.15.0.0	467 AD	Initial Series
Altar 1	10.0.0.0.0	571 AD	Period Ending

Although no new monuments were discovered, the missing middle and bottom fragments of Stela 15 were located. Maler had found the top of this monument on his fourth visit to Piedras Negras in 1899, but

was unable to locate the remaining pieces. Dr. Morley on his two previous visits to the site, in 1914 and 1921, had even failed to find Maler’s top, but this year not only the top was refound, but the middle and bottom pieces as well were located for the first time.

Stela 15 dates from the Great Period of the Old Empire, and is a magnificent example of ancient Maya sculpture, executed at the very moment of esthetic apogee. The relief is so high, 8 to 9 inches [20.3–22.9 cm], that the human figure carved on the front stands almost free of the background, the sections under the armpits being completely cut through and the upper arms appearing in the full round. The head is surmounted by a gorgeous panache of falling plumes; the hands are clasped in front of the figure, holding a bag or pouch upon which is beautifully carved the day 5 Ahau, the day of the Initial Series on the left side, viz, 9.17.15.0.0, 5 Ahau 3 Muan; the feet stand at an angle of about 90 degrees. The other costume accessories, collar, pendants, wristlets, anklets and sandals, are executed with great feeling and delicacy, and it may be fairly claimed that this monument is one of the finest examples of Maya plastic art, which has survived the vicissitudes of time.

The sequence of the hotun markers at Piedras Negras, the monuments erected at the ends of successive 1800-day periods, is the most complete in the Maya area. At no other city was the custom of celebrating the ends of the successive hotuns by the erection of sculptured monuments so rigidly followed; at no other city is the monumental series so regular and uninterrupted over such a long period of time. Indeed, the results of Dr. Morley’s investigations indicate that for a period of more than two centuries, that is, from 9.8.15.0.0 to 9.19.0.0.0 (349 to 531 AD) no single hotun-ending was permitted to pass without the erection of a corresponding sculptured monument.

27.0. QUIRIGUÁ

Frederick Catherwood visited the ruins at Quiriguá in 1840 and spent one day at the site sketching two of the stelae. John Lloyd Stephens reported Catherwood's trip to Quiriguá in his famous 1841 book. Alfred P. Maudslay visited Central America for the first time in 1881 and Quiriguá was the first ruin he visited. He stayed at the site for three days on his first visit, but he returned on three other occasions through 1894, when his wife accompanied him. During these trips he felled the large trees, cleared the bush, photographed the monuments, and made molds of the sculpture. He also made drawings of the figures and glyphs and on later trips compared them with the originals. In addition, he surveyed and partially excavated the site core. Further work was done at the site from 1910 through 1914 under the direction of Edgar Lee Hewitt for the School of American Archaeology of the Archaeological Institute of America. Shortly thereafter, the Carnegie Institution of Washington supported work off and on from 1915 through 1934. Sylvanus G. Morley, Oliver G. Ricketson, Earl H. Morris, and Gustav Strömsvik were important contributors during that time. The United Fruit Company, which by then owned

the land on which Quiriguá was located, in 1910 set aside 75 acres [0.3 sq km] surrounding the site core to be maintained as an archaeological park, leaving the jungle untouched in the middle of the banana plantation.

Quiriguá was one of the first Maya sites to be so thoroughly studied, though little of the architecture was restored. The structures that Morley had cleared and excavated once again became overgrown with jungle vegetation. In 1975 an intensive excavation and restoration program was begun under the direction of William R. Coe and Robert J. Sharer, jointly sponsored by the University Museum of the University of Pennsylvania, the National Geographic Society, and the Guatemalan government. It continued through 1979. During this work the acropolis was excavated, the monuments were cleaned and preserved, the outlying groups were studied, and Monument 26 was discovered.

27.1.

SYLVANUS G. MORLEY

Archaeology

YB 18:317–321, 1919

The principal work of the 1919 field season was the excavation in May of Temples 3 and of the Temple Plaza at Quiriguá, Guatemala. The excavation of this important group of buildings, no less than the civic and religious center of the site, as commenced 30 years ago by Mr. A. P. Maudslay, at which time Temple 6, on the north side of the plaza, was partially cleared.

Through an arrangement with Dr. E. L. Hewitt, Director of the School of American Research, Mr. Morley completed the excavation of this group during the present season. A plan of the temple plaza, which is 160 feet [48.8 m] long by 142 feet [43.3 m] wide, and the associated structures is shown in Figure 27.1.1, and a perspective drawing of Temples 1, 2, 3, and 4 (restored), looking southward, is given in Figure 27.1.2.

The excavation of Temples 3 and 4 brought to light no new hieroglyphic texts like those in the doorways

and on the cornice of Temple 1, but certain interesting architectural features were uncovered, perhaps not the least of which was the discovery that the old builders had begun to distrust their own handiwork, even in ancient times. Both temples, it was clear from the excavations, had begun to fail structurally before the city was abandoned, particularly at the corners, which had been prevented from sagging only by the erection of heavy buttresses built against the outer walls.

Temple 3 is the better preserved, due to the fact that the level of the terrace upon which it was originally built was subsequently raised at the back and sides to the level of the medial cornice, thus half burying the temple, all save the front, in a solid mass of stone and red clay, the only bonding material used in the Quiriguá masonry (Fig. 27.1.2). This resulted in its being better preserved than Temple 4, as already noted, and permits the establishment of one important architectural fact, namely, that the upper zone above the medial cornice, in this building at least, was vertical and not sloping as in the Palenque temples and the second story of the Monjas at Chichén Itzá. Temple 2 nearby has the same feature, and in the restoration in Figure 27.1.2 all the temples except no. 1 are shown with a vertical wall above the medial cornice.

Figure 27.1.1. Quiriguá, plan of the Temple Plaza and associated structures.

Figure 27.1.2. Quiriguá, Temples 1, 2, 3, and 4, looking southward (restored).

The façade had been ornamented with an elaborate decoration in stucco which was entirely destroyed when the roof collapsed, many small fragments of which were recovered during the excavation of the terrace in front of the temple.

The plaster on the floors and interior walls was of lime, fairly hard, and had been painted a dark wine-red. Some traces of green were also found in the doorway.

The most interesting feature of Temple 3 was the small dark interior chamber which was entered by a low passage 3 feet 6 inches [1.1 m] high, from the north chamber. It is only 3 feet 10 inches [1.2 m] high, 2 feet 8 inches [81 cm] wide, and 4 feet 9 inches [1.5 m] long. Strange to say, it was intact when found, every roof stone being in place, and it was half full of red earth lightly packed, as was also the passageway giving access to it. This was due to the leaking through of water from above, carrying with it particles of the red-clay bonding material, which gradually filled the chamber. Not a single specimen was recovered from this chamber, the use of which remains problematical.

A similar chamber was found in the excavation of Temple 2 in 1912, and at its farther end were 12 or 14 rounded river pebbles weighing a pound or more each and showing signs of having been smoked by fire. It has been suggested that these may have been heated and dropped into bowls containing water, thus making vapor, and that the chamber itself was used in connection with some sweating ceremony.

The most important architectural feature of Temple 4 was the interior stairway leading from the northern chamber to the roof. This was composed of two flights of steps and a landing. The first flight is 2 feet 2 inches [66 cm] wide, and has four steps averaging 9 inches [22.9 cm] in height. Beyond the landing the stairway make a 90 degree turn to the left, and then continues 2 feet 8 inches [81.3 cm] wide for five steps more to the top, the steps averaging one foot [31 cm] in height. The

roof was gone, but it probably had been like that over the interior stairway of Temple 20 at Copán, that is, composed of successively higher sections of the typical corbelled arch roof. The original height of Temple 4 is preserved to within 6 inches [15.2 cm] at the top of this stairway, from which it may be estimated to have been about 12 feet [3.7 m] high.

The specimens found, as is usually the case in temple excavations in the Maya field, were rather meager: a clay-pipe, two shell rings, two jade beads, parts of a very fine alabaster bowl covered with a brilliant red paint almost like an enamel, parts of a human skull found in the doorway of Temple 3, animal and bird bones, many obsidian flakes, a number of broken pottery vessels, and two fragments of a vase showing a band of hieroglyphs carved around the neck just below the rim.

The ground-plans of the several temples in Figure 27.1.1 show a general similarity in the arrangement of chambers between Temples 1 and 3 on the one hand and Temples 4 and 5 on the other; Temples 2 and 6 being different, not only from either of these two pairs, but also from each other. On the other hand, none of them contained large numbers of chambers, like some buildings elsewhere in the Maya area, for example, the Palace at Palenque or the Monjas at Uxmal; and it is probable that all were used either as temples proper, that is, places where religious rites and ceremonies were carried on, or for administrative purposes, such as councils, courts, and the like; and finally, probably none of them were dwellings of rulers or priests, such as the Palenque and Uxmal structures mentioned may have been.

The date of erection of the temple plaza is not certain, although Temple 2 is clearly the oldest of the six structures surrounding it. The apparent correlation of Zoomorphs O and P, 9.18.0.0.0 and 9.18.5.0.0, respectively, with the northern extensions of the terrace of

Temple 5, might indicate that one or the other marks the completion of this part of the group. The dedication of Temple 1, the only one of the six buildings having sculptured decoration, and therefore probably the latest, in 9.19.0.0.0, marks the end of sculptural as well as architectural activity at Quiriguá, this site (along with other Old Empire cities then occupied) probably having been abandoned not long thereafter.

27.2.

OLIVER G. RICKETSON

Excavations at Quiriguá

YB 32:95–96, 1933

The greater part of [1932–33] was spent by Dr. and Mrs. Ricketson in Guatemala City, completing their report upon Uxactún, in which Mr. Ricketson describes the excavations and Mrs. Ricketson treats the pottery and other artifacts. In the spring of 1933 Dr. Ricketson spent two weeks at the ruins of Quiriguá in the lower Motagua Valley to report upon the feasibility and probable expenses of making the ruins into an accessible and properly protected national park; to determine, if possible, subplaza conditions, especially with regard to stratification, either natural or manmade, by which the successive periods of occupancy could be distinguished; and to collect sherds from successive strata, if any, for comparison with the ceramic sequence obtained at Uxactún.

In order to determine whether the ruins of Quiriguá merited a more or less intensive archaeological examination, especially from a ceramic standpoint, eight pits were sunk within the ruins proper, five in the Main Plaza, one in the Ceremonial Plaza, and two in the Temple Plaza at the extreme south. Every pit in the plazas proper disclosed natural river cobbles as pavement underlying silt accumulated since the monuments were erected. The average depth of this silt is 0.96 m. Five of the six pits struck clay at an average depth of 2.7 m beneath the present surface and a sixth, Pit 2, pierced a clayey sand which gradually merged into a sandy clay at about 3 m. Pits 3 and 8 exposed butts of stelae, both of which were erected in rock ballast, about the only method possible for the erection of large and tall monoliths in such soft soil as composes the plaza. The deposits contained a disappointingly

small number of potsherds, most of which came from below or in the topmost pavement. They are being studied by Mrs. Ricketson.

27.3.

EARL H. MORRIS AND

GUSTAV STRÖMSVIK

Quiriguá

YB 33:86–89, 1934

The ruins of Quiriguá, in the valley of the Motagua River, Guatemala, date from the Great Period of the Old Empire. The site is remarkable for the size and extraordinarily beautiful sculpture of its stelae and altars. Quiriguá lies on the railroad from Puerto Barrios to Guatemala City and is much more easily accessible of all Old Empire centers. Hence it is essential to do everything possible to safeguard the monuments from deterioration and to render them readily examinable by visitors, in order that they may serve as an example of Maya art at its apogee. They stand in an area of magnificent tropical forest left intact as a proper setting for the ruins by the United Fruit Company, when it cleared the surrounding region for banana culture. The Company has also kept clear of vegetation the plaza about which the monuments are grouped. Several of them, however, had come to the ground in former years and some had been broken, evidently by the fall of great trees. In mending and re-erecting those which were down and in examining the foundations of those still standing, Mr. E. H. Morris and Mr. Gustav Strömsvik spent four months at Quiriguá in the winter of 1934. Their undertaking, encouraged and sanctioned by the government of Guatemala, had as collateral scientific purposes the investigation of the methods by which these very large monoliths had been set up and a search for the ceremonial caches often found buried below a Maya stela.

Mr. Morris and Mr. Strömsvik straightened the leaning Stelae A and K; re-erected the complete Stelae E and I; and re-erected and mended the broken Stelae H and J. They also found caches in connection with several stelae and zoomorphs. The outstanding event of the season was the discovery of two sculptured altars, one in front of Zoomorph P, the other in comparable position to Zoomorph O. Many very difficult engineer-

ing problems were encountered in handling the tremendously heavy monoliths, and the utmost caution had to be exercised to guard against marring the high relief sculpture with which they are covered. All phases of the work were much facilitated by cordial cooperation on the part of the personnel of the Guatemala Division of the United Fruit Company.

The straightening of Stelae A and K involved the use of fairly simple mechanical procedures. Earth and masonry were cleared away from the upper sides of their bases sufficiently to permit the movement necessary to bring them back to vertical position. Stela A was drawn upright with a chain block anchored to deadmen. Stela K was pushed straight with screw jacks, because its shaft was so full of cracks that a pull against the top probably would have reduced it to fragments.

The uprooted Stelae E and I were erected as follows: a pit was dug beneath the butt of each to appropriate depth, and in the bottom of it a concrete foundation was poured. A huge A-frame of native timbers was put up to span the pit. From a point well toward the tip of the stone shaft, a steel cable was attached to the top of the A and fastened to another steel line, which, rove through double blocks, connected with the drum of a ratchet-action hand winch. Stay lines were provided at the sides of the stela to prevent lateral swing during upward movement and a rear stay to forestall possible forward collapse after the vertical had been attained. The re-erection of Stela I was comparatively simple, since the stone was short and weighed only 17 tons. In contrast, Stela E was the most formidable of the monuments, its length being 35 feet [10.7 m] and its weight some 50 tons. Once in upright position, each shaft was secured by pouring a sturdy collar of concrete into a pit which had been dug to receive the base.

Stelae H and J had leaned considerably before their shafts snapped off at or slightly above ground level. The first step in the process of re-erection was the straightening of the bases. The masonry fill was dug away around them; the butts were shoved upright with jacks and anchored with concrete collars. The several main portions had not only to be swung to a standing position, but in addition had to be raised vertically in order that they might be set down in proper alignment on their butts. The lifting was accomplished with the hand winch, its draw-line operating through double blocks suspended from a four-legged derrick of native timbers. Heavy iron dowel pins were set across the lines of fracture and the bores enclosing them filled with liquid cement.

Great care was taken not to injure the sculptured surfaces. Where the collars for draw-lines were to be applied, thick mattresses of dried banana leaves were

lashed to cover the stone. Over this padding, a thick layer of split timbers was bound on and, outside this at right angles to the longer axis of the timbers, the encircling cable was applied.

Necessary excavation around the butts brought to attention several points of interest. Every stela in the city, with the possible exception of A, C, and D, stands at the center of a rectangular platform some two feet higher than the surrounding court level. The margins of the platforms are composed of very large sandstone blocks neatly cut and fitted. At the point where a stela was to be set up, a pit was dug to a depth of several feet below court level, then filled solid with masonry laid in clay except for a faced well at the center. Masonry was spread over the bottom of the well and covered, sometimes with a single very large flat stone, or in other cases with three or more smaller ones to serve as a bearing plane for the shaft. After the latter had been raised on end, the space between the butt and the sides of the well was wedged with masonry. The buried butts ranged in length from 3.5 to 8 feet [1.1–2.4 m]. No empirical evidence was obtained to suggest the method by which the Maya set the stela upright.

Below ground on Stelae A and E, "quarry stumps" remained to reveal the method by which the huge blocks had originally been separated from the mother rock. The surface of a ledge was cut straight and smooth. Then the desired block was outlined by a ditch which was deepened until a mass the height of the determined width of the shaft stood free. Subsequently the mass was undermined from back and front and cut through at regular intervals until the beam of stone remained poised upon and connected with the ledge below by a series of slender stumps which could be snapped off by prying with levers.

The Quiriguá zoomorphs proved also to rest upon constructions that had raised them considerably above what had been court levels previous to the deposition of the river silt that now hides the bases. Zoomorphs B, G, and O each recline upon a series of three enormous stone beams, placed transversely to the block above them and bedded on the gravel court. Zoomorph P has beneath it one very large sandstone slab with a row of smaller pieces rimming its periphery.

A search for caches pertaining to the sculptured monuments was one of the definite objectives of the Quiriguá expedition. Deposits were found near or beneath the following monoliths: Stelae E, H, I (by O. G. Ricketson in 1933) and J; Zoomorphs B, G, O and P. Excavations around the bases of Stelae A and K did not reveal caches, but it is probable that had digging in these cases been as extensive as at the other sculptures above mentioned, offerings would have come to light in connection with them also. From the fact that in every case where the test was conclusive, some sort

of deposit was found, it is indicated that at Quiriguá it was the universal practice to enter an offering during the erection of each monument.

In five cases (Stelae E, I, J; Zoomorphs G and P) the imperishable components of the offerings were rectangular pottery boxes 12 to 14 inches [30.5–35.6 cm] long and from 12 to 17 inches [30.5–43.2 cm] high, each fitted with a pottery lid shaped like a mansard house roof. All were empty save the one from Zoomorph G, which contained one very large obsidian core. In a slender cylindrical pocket in the gravel court paving below Zoomorph B, there was a sheaf of seven flint blades and four pieces of unworked jade. The blades are of superb workmanship, shaped like willow leaves, and vary in length from 5.5 to 18.3 inches [14.0–46.5 cm]. Deep down beside Stela H was one of similar shape, 9 inches [22.9 cm] long. In the lowest level of the clay-gravel paving under the foundation of Zoomorph O was embedded a quartz crystal, an unworked bit of jade, a jade face 1.25 inches [3.2 cm] long of superlative craftsmanship and a flint dagger 8.75 inches [22.2 cm] long, its handle shaped like the curve of a capital D, and wrought to represent the body and head of the Plumed Serpent. The corner where the blade and handle emerge is chopped into a typical Maya profile.

The most unexpected development of the season was the discovery of sculptured altars in front of Zoomorphs O and P. These lay directly under the principal trail from the railway to the Temple Court, hidden by 18 inches [45.7 cm] of silt. The one in front of Zoomorph P was found in sinking a shaft from which a tunnel might be driven beneath the zoomorph in search of its cache. The discovery of the first altar dic-

tated the quest of another in comparable position to the nearby Zoomorph O. Trenches failed to reveal altars in connection with Zoomorphs B and G at the opposite end of the city.

The stones are great slabs of somewhat irregular outline, carved on top and sides with compositions that were skillfully planned to conform to the topography of the available block. The altar pertaining to Zoomorph P is 11 feet 8 inches [3.5 m] in greatest length, 10 feet 6 inches [3.2 m] in greatest width and 1 foot 9 inches [53.4 cm] thick. Equivalent dimensions of the one accompanying Zoomorph O are 12 feet 4 inches [10.8 m], 11 feet [3.4 m], 1 foot 8 inches [50.8 cm]. The dominating figure in each carving is a large human form in dancing posture, elaborately clad and wearing a huge and complicated headdress with face mask. The other two-thirds of the area is covered with a long and delicately wrought hieroglyphic inscription, the whole margined with serpent motifs. The carvings, in composition and execution, are in the best Old Empire style. They will take rank among the masterpieces of Maya art.

While the work on the stelae was going on, Dr. Ricketson visited Quiriguá to examine ancient water-gathering devices discovered by the United Fruit Company during the digging of drainage ditches. Each of these proved to consist of a single large jar-shaped pottery vessel with perforated bottom, sunk to the level of ground water and set in a mass of rocks. The jar was connected with the surface by means of sections of cylindrical pottery pipe. The grouting of rock permitted water to filter through the jar, at the same time excluding silt. Access to the collected water was had through the cylindrical pipe.

28.0. UAXACTÚN

Uaxactún is located in the Petén region of northern Guatemala, some 40 km north of Tikal. With the decipherment of the Maya hieroglyphic writing, it was discovered that the ancient name for this site was Siaan Kaan. The name "Uaxactún" was given to the site by Sylvanus G. Morley in May, 1916. He coined the name from Maya words to mean Eight Stone. The name has two meanings: Morley's stated reason for the name was to commemorate it as the first site where an inscription dating from the 8th baktun of the Mayan calendar was discovered (making it then the earliest known Maya date). The other meaning is a pun, since Uaxactún sounds like Washington, home of the Carnegie Institute which funded Morley's work.

The first archaeologist to visit Uaxactún was Morley, when he headed an expedition for the Carnegie Institution of Washington in 1916. It is not clear how he first heard of the site, but he was guided there by a man named José. Although Morley and his team were at the site for only six days, they examined, photographed, and made drawings of the glyphs on several carved stelae, took measurements for a site plan, and did sketch plans of the structures. In 1924

Frans Blom spent two months at Uaxactún, surveying the site and recording the architecture and sculpture. He was the first to suggest that Structures E-I, E-II, E-III, and E-VII might have functioned as a solar observatory. From 1926 through 1937, the Carnegie Institution of Washington team, including Oliver Ricketson and Edith Bayles Ricketson, A. Ledyard and Robert E. Smith, and Edwin M. Shook, conducted excavations at the site. Ceramic analyses were undertaken by Robert E. Smith, and Alfred V. Kidder studied the artifacts. For most of the CIW team's time at Uaxactún, communication with the outside world was via a four day mule convoy to El Cayo, Belize. Towards the end of the time an airstrip was opened up. Flights to Uaxactún continued and a small village grew here, as it became a center for gathering of chicle sap from the Petén jungle.

A. Ledyard Smith and Shook returned in 1940 to resolve some points. In the late 1970s a rough road was opened up, connecting Uaxactún to Tikal and to the departmental capital of Flores, Guatemala. Air flights were later discontinued, and in 1974 Shook recleared and restored Structure E-VII-Sub. In 1978 Anthony Aveni took astronomical

measurements at the Group E solar observatory, and in 1978 and 1979 Ian Graham recorded the carved monuments. In 1982 a program of stabilization and restoration was begun by the Instituto de Antropología e Historia de Guatemala, and in 1983 Guatemalan archaeologists began new investigations, and in 1985 vaulted structures and stucco masks were discovered in Group H.

Uaxactún is one of the most extensively investigated sites since the early years of Maya studies. The ceramic sequence that resulted from the early Carnegie work there laid the foundation for the whole of lowland Maya chronology. This chronology was then linked to that of most of the remainder of Mesoamerica. Uaxactún's ceramic sequence begins early in the Middle Preclassic period, at which time platforms were constructed. Structure E-VII-Sub and vaulted structures were built during the Late Preclassic. Uaxactún was an active center in the Early Classic Period; then it was conquered by Tikal and ruled by Smoking Frog. Near the end of the Late Classic Period, a stela dating to 889 AD was erected at Uaxactún. It is one of the latest dated monuments in the southern Maya lowlands. In 1982 Guatemala's Tikal National Park was expanded to include the ruins of Uaxactún within its protected area.

28.1.

FRANS BLOM

*Report on the Preliminary Work at
Uaxactún, Guatemala*

YB 23:217–219, 1924

The eighth expedition of the Carnegie Institution into the Department of Petén, northern Guatemala, left Belize, British Honduras, for El Cayo, the head of navigation on the Belize River on February 18. The object of the expedition was to make a survey of the ruins of Uaxactún, discovered by the expedition of 1916, and to prepare the site for exploration during the coming years.

El Cayo, the chicle and mahogany center on the Belize River, is the starting point for all expeditions wishing to penetrate the immense tropical forests of northern Guatemala. It was reached on February 21. Pack-mules were secured and final touches were put to the outfit. Plancha de Piedra, the Guatemala customs station, was reached on February 25, and the following day 22 saddle and pack animals and a gang

of laborers on foot, swung into the narrow forest trails. Four days brought the expedition to its destination.

Mr. O. G. Ricketson, who had previously been at Uaxactún, accompanied the expedition in order to acquaint the leader, Mr. Frans Blom, with the ruins and monuments. As soon as this was accomplished he returned to British Honduras.

Dense vegetation covered the site, and it was necessary to clear this in order to erect houses, roofed with palm leaves, for the members of the staff and the workmen. A large water-reservoir had to be dug in the water-hole, which generally dries up during the month of May. As soon as a camp was established and trails had been cut to the different groups of buildings, a plane-table survey of the ruins was commenced. Mr. Monroe Amsden started this work but, as he soon had to leave because of illness, it was completed by Mr. Blom.

Toward the close of April, work at Uaxactún was concluded and the greater part of the equipment was sent direct to Plancha de Piedra. Mr. Blom, with some Indians, proceeded to various other ruins in the Department, finally reaching El Cayo on May 18. The sites visited were Tikal, Mejia, (new), Ixlú, Flores, Tayasal, Chichantún, Yaxhá, Topoxté, Benque Viejo, caves near Benque Viejo, Nakúm, El Encanto, Holmul, Tzotzkitam, and Baking Pot, the last in British Honduras.

Though the primary purpose of the expedition was to prepare for more intensive work at Uaxactún, a large amount of archaeological information was collected.

All the monuments at Uaxactún carrying inscriptions were drawn. A comparison of these drawings with those previously made by Dr. Morley made it possible to definitely decipher several, formerly doubtful dates. Stela 5 at last gave up the secret of its date, the reading being a Baktun 8 Initial Series, 8.16.1.0.12. Dr. Morley had previously given the tentative reading 8.15.18.3.12. This final reading gives a third Baktun 8, Katun 16 date at Uaxactún.

On a fragment of Stela 14 the date 8 Ahau 18 (?) was found; this may well be 9.19.0.0.0, 8 Ahau 18 Mol, the same date as given by the Initial Series on Stela 7 here.

The plane-table survey disclosed several important features, among others the close relation between Groups A and B, through an inclined road connecting the main plazas of the two groups. This road emphasizes the importance of the main plaza of Group A. The mound at the southern side of this plaza appears to be the heart of the two groups. This mound faces north, and from its top one looks down upon the main plaza of Group A and a row of monuments including Stelae 7, 8, and 11. The oldest stela known stands on the northern side of this plaza, and to the north of it begins the road already mentioned, sloping down to

the main plaza of Group B, with its multitude of monuments, a most imposing sight in ancient times.

During rainy days the large temple standing at the northeastern corner of the Acropolis (Group A) was cleared. The floors were covered with several feet of fine dust, and this was removed. Two rooms in the western end of the temple were nearly filled with debris, and when cleared the more western of these was found to contain a stairway turning at right angles and leading to the roof of the building. Only one other such stairway had been previously known, that discovered by Dr. Morley at Quiriguá. This building is in such a good state of preservation that it will be used for staff quarters.

On the lowland close to the aguada a quarry was found, which shows distinctly where the ancients had cut a limestone block for a stela. The road connecting Group A with Group D, as well as other roads connecting the different parts of Group D, was also found.

By far the most important discovery was made in Group E, namely, what appears to be an observatory for studying the sun. The group consists of terraces on which are mounds, the terraces being arranged around a plaza. The eastern terrace has three mounds upon which are remains of temples (I-III) with stairways leading from the plaza. In front of this terrace are Stelae 18, 19, and the plain stela, F.a. Whether we really have an observatory here can not be determined until the group has been excavated and studied with precise instruments. The figures at hand speak in favor of an observatory.

On the western side of the plaza we found Mound VII, likewise crowned by the remains of a temple facing south. On the side of this mound toward the plaza stands Stela 20. This plaza was covered with dense vegetation, and as the work of clearing proceeded it became more and more apparent that there was a close relation between Mound VII and Stela 20, and the eastern terrace, with its three mounds and three stelae.

The Department of Terrestrial Magnetism has located the geographic position of Uaxactún as latitude north 17 degrees 23' 8", and longitude west 89 degrees 38' 4". The bearings within the group were taken with a Brunton Pocket Transit from a position directly behind (i.e., west of) Stela 20. The magnetic declination is 7 degrees and was corrected on the compass, so that all readings were taken direct. A line drawn between Stela 20 and Stela 19 turned out to be due west-east, cutting through the center of Temple II.

Sights were also taken from Stela 20 to Stela 18 and F.a., the bearings being N76 degrees E. and S 76 degrees E respectively, and finally sights were taken over the centers of the Mounds I and III, giving the bearing N 66 degrees E and S 66 degrees E, or 24 degrees north and south of the west-east line. Compari-

son of these angles with the following data furnished by the Department of Terrestrial Magnetism shows amplitudes for sunrise at Uaxactún in latitude 17 degrees 23' 8" north and longitude 89 degrees 38' 4" west of Greenwich extreme values during the year.

Table 28.1.1. Amplitudes for Sunrise, Uaxactún.

<i>True Horizon</i>	<i>Visible Horizon</i>	<i>Remarks</i>
24.6	24.4	North of east on June 22.
24.6	24.9	South of east on December 22.

We see that the lines of sight from Stela 20 to Stela 18 and F.a. are 24 degrees north and south of the true east, coinciding with the two extremes at which the sun rises during the year.

Turning to the dates on the three stelae in Group E, we see that Stelae 18 and 19 carry the same date, viz, 8.16.0.6.0, 3 Ahau 8 Kankin (97 AD) and Stela 20, the date 9.2.0.0.0, 2 Ahau 18 Muan (235 AD). If Group E really proves to be a sun observatory it must have been erected not later than the year 235 AD and have been planned long before the two earlier stelae set up. Excavation of this group may throw much light upon Maya astronomy; it may be possible to find other lines of observation, and to determine the unit of measurement used, etc.

A hitherto unknown group of huge mounds was located south of Group E, and called Group F. A large natural hill had been leveled and terraced. Mounds inclosing courts and remains of several buildings were found, but no monuments.

28.2.

SYLVANUS G. MORLEY

The Uaxactún Project

YB 25:273-274, 1926

The current year witnessed the extension of archaeological operations to Guatemala. On November 28, 1925, a contract was signed in Guatemala City by Señor Don Rafael Ordoñez Solís, the Minister of Public Education, representing the Government of Guatemala, and by James H. Roach, an American citizen resident in Guatemala under special power of attorney, in behalf of the Institution.

Under terms of this contract, the Carnegie Institution acquires the right to carry on exclusive archaeological investigations, including excavation, at the sites of Uaxactún and Tayasal in the northern central part of the Department of Petén, and general exploratory privileges at all other sites in the same department, the heart of the Old Maya Empire, for a period of five years beginning January 1, 1926, with an option for renewal for an additional period of five years.

This contract, together with the one in force with the Mexican Government, brings under the Institution's purview possibly the three most strategic sites for a comprehensive study of the Maya civilization that can be found. Uaxactún is the oldest city of the Old Empire now known, based upon the evidence of the dated monuments (68 to 630 AD). Chichén Itzá is the oldest city of the New Empire, and was apparently the second place of any importance to be founded in the peninsula of Yucatán (531 to 1448 AD).¹ Tayasal was the last independent Mayan stronghold, and resisted the Spanish arms for a century and a half after the Conquest of Yucatán (1448 to 1697 AD). It has the further intimate connection with one of the other two sites, in that it was founded by the Itzá after the destruction Chichén Itzá, thus bringing under the Institution's observation and study six continuous centuries of ancient Maya History.

The Uaxactún Project was organized in January and Dr. Morley's direction, and on January 9, O. G. Ricketson, Jr., assistant archaeologist, sailed for Belize, British Honduras, to take charge of the field work at Uaxactún. Monroe Amsden joined him in February as field assistant, and a fortnight later the expedition proceeded by way of the Belize River to Plancha de Piedra on the eastern frontier of the Department of Petén, and thence overland by mule to Uaxactún.

Work at this site has been rendered far more practical and economical through the opening up of the whole region by the P. W. Shufeldt Company, a corporation engaged in the chicle business, to which the 1926 expedition is greatly indebted. Not only did this organization handle the transportation of all food and supplies, at cost, but its agents at El Cayo and Laguna Yaloch were instructed to extend credit to the expedition and to forward mail by their couriers. The expedition is also much indebted to C. O. Taylor, of Belize, for his many kindnesses, and to Robert Masson for his courtesy in expediting the customs inspection of scientific equipment.

On March 8 all available men were set at work clearing Group E, the site chosen for preliminary excavation. This group was first reported by Dr. Morley in 1922 [Chapter 1.10 this volume]. In 1924 Mr. Blom stated that the group was of unusual interest, as it contained lines of sight marking the sunrise points at

the solstices and the equinoxes [Chapter 1.12 this volume]. On March 10, four trenches were started into Mound II, two from the north and two from, the south. This mound is 60 feet square, and is one of three, which rest upon an artificial substructure 210 feet long by 90 feet wide. Mound II was partially excavated, the north and south ends being uncovered, and the many large tree stumps on its top and sides cut out.

On April 20, the corn-field was burned, and immediately afterward all 12 laborers were put to work building a permanent bush house, kitchen and corral. Work was rushed, in order that it should be completed before the water in La Joventud aguada should be exhausted, as the drying up of this aguada would necessitate the immediate withdrawal of the expedition. The buildings were completed May 18, a caretaker was installed, and the expedition left Uaxactún on May 19 for the exterior.

NOTES

1. The second place-name mentioned in the *ukahlay katunob* or native chronicles in the Books of Chilam Balam, which it is possible to associate with a definite geographical locality today, is Chichén Itzá (Brinton 1882:101, 144, 158).

28.3.

OLIVER G. RICKETSON

Report on the Uaxactún Project

YB 26: 256–263, 1927

In conformity with the contract granted by the Government of Guatemala to the Carnegie Institution of Washington for the excavation of the ruins at Uaxactún [Chapter 28.2], the second season was inaugurated early in January 1927. The members of the expedition consisted of Oliver G. Ricketson, Jr., in charge, Monroe Amsden, assistant, Mrs. Ricketson, and A. Ledyard Smith.

The purpose of the 1927 field season was to determine, if possible, the functions of Group E, reported in 1924 by Frans Blom as being in all probability a solar observatory [Chapter 28.1]. Group E consists of a plaza, the long axis of which runs north and south, 308 feet 5 inches [94 m], and the short axis east and west, 150

feet 10.5 inches [4.6 m], bounded on the east by a platform mound, 234 feet 8 inches [71.5 m] long at the bottom and 15 feet [4.6 m] high, on which stand Temples E-I, E-II and E-III. It is bounded on the south by another platform mound on which stand Temples E-IV, E-V and E-VI, and on the west by a pyramidal structure, E-VII, which is 50 feet [15.2 m] high. On the north are four mounds, E-VIII, E-IX, E-X and E-XI, surrounding a small court known as the North Court of Group E. The plaza contains four stelae, 18, 19 and E-I on the eastern margin and 20 in front of Pyramid E-VII.

During 1927, excavations were concentrated on the astronomically significant elements of Group E, with the result that the ground plans of Temples E-I, E-II, and E-III were determined, as well as the stairway and base of the platform on which these temples stand. The north and east sides of the base of Pyramid E-VII and its stairway were also uncovered.

Pyramid E-VII was found to be without a structure on its top and with its stairway on the east.¹ Its construction was of the crudest sort, consisting of rough, broken stones covered with crumbling plaster. Under this disappointing exterior, however, an earlier pyramid was discovered, built in terraces of well-wrought stone covered with plaster, still in excellent condition. Less than a week before the withdrawal of the expedition, made necessary by the exhaustion of the water supply, a mask was uncovered on the eastern face of this inner pyramid, just north of the stairway of the outer one. This mask was about 8 feet square [0.7 sq m], and represented a human or a humanized-animal head. It was constructed of stucco laid over a masonry core. The nose was extremely broad and flat, with a transverse, tapered decoration hanging in a catenary curve from the internal acanthi of the two eyes. The pupils of the eyes were represented by two vertical raised bands. The mouth, extending nearly across the whole face, showed as a narrow, sunken slit, with two curling fangs hanging from beneath the canine teeth, which were also shown. In the center of the mouth were two incisors, overlaid

Figure 28.3.1. Uaxactún, Group E, Pyramid E-VII, Stelae 19 and 20, and Temple E-II, plan and section.

with a triangular device roughly heart-shaped, the rounded apex pointing down and the base contiguous with the upper lip. Only the right ear was exposed; it was represented by shallow incised lines and molding, and had a pointed tip and a flare that is suggestive of a bat's ear. The head was covered with the conventionalized representation of a feather head-dress. The execution of the whole is good, though markedly primitive. It is not done in bold relief. Further excavation of this mound will reveal other masks symmetrically placed, and will be necessary before a final report can be written.

When the debris in front of Pyramid E-VII was cleared, Stela 20 was found to stand on a raised dais, 1 foot 10 inches [55.9 cm] high. The stela is 6 feet 11 inches [2.1 m] in front of the bottom step of the stairway.

Temples E-I, E-II, and E-III, on the east side of the plaza, were found to be in such a dilapidated condition that the greatest difficulty was encountered in finding the remains, of walls. Each temple stands on a platform 10 feet high. The substructure terrace, upon which all three are located, is 15 feet [4.6 m] high, and

is ascended by a central stairway, 34 feet 6 inches [10.5 m] wide and consisting of 16 steps, on the west side.

Temple E-I, like Temple E-II, faces W 0 degrees 3' N.² It consists of a small, two-room building reached by a central stairway of eight steps. The inner room is higher by a step of 1 foot 2 inches [35.6 cm] than the anterior room, and is divided by an altar against the back wall in such a way that it appears to be three very small rooms. This altar consists of a rectangular block 2 feet [61 cm] high, with L-shaped walls enclosing the two sides and partly enclosing the front.³ One step is cut into the edge at the entrance. Excavation in the altar itself revealed a nest of potsherds. The pots of which they were fragments had evidently been broken before they were put into the altar, as it was impossible to assemble even one whole piece, though the sherds were very carefully collected. Here were found the sherds which, when pieced together, made the fragment with the beautiful and unusually colored painting of three Maya priests in full regalia. The colors used on this sherd were black, grey, white, yellow ochre, red, crimson, dark brown and a rose pink which the writer has not seen elsewhere in Maya pottery.

South of the altar in Temple E-I, in a circular hole in the floor, Cyst 2, 1 foot 6 inches [45.7 cm] deep and 1 foot 6 inches [45.7 cm] in diameter, were found two plain redware dishes with flaring rims, the upper one inverted over the bottom one. Each was 12.5 inches [31.8 cm] in diameter at the rim, and about 4.25 inches [10.8 cm] deep. They enclosed some fragments of bone, a complete set of human teeth, nine small jade beads, two small, irregular jade ear-plugs and a jade pendant representing an animal head. All of the jade pieces were of inferior material and workmanship. Similar burials were found in like positions in the other temples of this group and will be described with the temples concerned.

Of the walls of Temple E-I, for the most part only the inner surface remained standing, and only between the front and back rooms could the thickness of the wall be measured. It was found to be 4 feet [1.2 m] in thickness. The walls of the anterior chamber and the outer facing over the rubble core of the building were entirely fallen, this condition being due not only to the age of this section of the city, but also to the poor quality of the limestone in this part of the Yucatán peninsula and to the size of the trees which have taken root in the ruins. The platform beneath Temple E-I was peculiar in that its southern retaining wall ran S 83 degrees 18' E, or at an angle of 96 degrees 45' with the front line.

Temple E-II was a more complex structure. It was evidently the chief temple of the group, and stands directly behind the main central stairway from the plaza to the top of the mound. Although now in a very

ruined condition, originally it seems to have been a four-room building on a platform, reached by ten steps, each 6 feet 6 inches [1.9 m] wide and about a foot [31 cm] high; at a later date walls were added in front of the platform on the level of the top of the substructure terrace. These walls, when excavated, were only 2 to 3 feet [61–91 cm] in height; whether they formed a typical Maya room with vaulted arch it is not possible to say, but the relative thinness of the walls, 2 feet 6 inches [76 cm] to 3 feet [91 cm], and the lack of any cut vault stones in the debris would seem to argue against this hypothesis. In the southern end of this enclosed space traces of a low shelf or bench were found and a large quantity of sherds.

From the back of this lower room or gallery, the steps above mentioned lead into the anterior chamber of the temple itself, and two more steps lead into the posterior chamber. This latter was divided into a middle and two lateral rooms by transverse walls pierced with doorways. The outer side walls in both of the lateral rooms had completely fallen, making it difficult to determine the original inside length, north and south, of the building. It was about 41 feet [12.5 m]. The central room contained a rectangular, plastered bench or altar, 8 feet 3 inches [2.5 m] deep by 8 feet 7 inches [2.6 m] wide by 1 foot 4 inches [41 cm] high, which, upon excavation, proved most interesting. Inside it were two other earlier altars, one built over the other. The earliest and smallest one consisted of a rectangular plastered block, 35 inches [88.9 cm] deep by 45 inches [114.3 cm] wide, with a basin-like depression in the center and two lateral walls framing it. These walls extended less than 18 inches [45.7 cm] forward from the back wall of the temple. The second altar extended the lateral walls to 57 inches [144.8 cm] from the back wall and completely covered the altar beneath. The second altar was 1 foot 1 inch [33 cm] high, painted red, and also contained a basin-like depression in the top. The third or outer altar completely covered the constructions beneath, though the lateral walls on the north and south had not been extended to the front margin but left as they were when the middle altar was constructed. The outer altar had been plastered many times, and painted differently each time, the most frequently occurring colors being red and gray.

Above the surface of the second altar and below the surface of the third, that is, apparently in the depression on top of the second altar, were found 71 small pieces of jade, all broken pieces, small useless chips of varying sizes and shapes. These were scattered throughout the rubble of the altar, as well as a large quantity of bones of small animals, bats and small rodents. In the southwest corner of this area a small red dish was found, upside down, and near it a

small red pottery disk, a bird's head of red pottery, with eyes and wattle appliquéd in the same material, and a few disassociated human bones and teeth, apparently of a child. In the latest part of the altar; that is, below the surface of the outer altar but beyond the margin of the second one, innumerable skeletons of bats and rodents were found in a very fine black dirt.⁴ Two very small and finely worked lancets of obsidian, 2 inches [5.1 cm] and 2.75 inches [7.0 cm] long respectively, were found among the bones and Mr. Ricketson believes that these were the instruments used to kill the small animal offerings. In the southwest corner of this altar were two, flat red-ware dishes with flaring rims, about 6.75 inches [17.2 cm] in diameter and 2 inches [5.1 cm] deep, the upper one inverted over the bottom one, as already described in Cyst 2, Temple E-I. These dishes contained a fine dust, apparently fragments of bone.

South of the altar and in the center of the south room of the temple, two more cysts, 6 and 5 respectively, were discovered in the floor. Cyst 6 contained two plain red-ware dishes with flaring sides, the upper one inverted over the bottom one. Between the dishes were a human cranium and atlas, in good condition when found. It seemed to be that of an immature person, possibly male. The two lower incisors were lacking and the bone healed over; the fronto-occipital deformation was slight; the teeth were unworn; there was visible a shrunken, brown, friable tissue in the nares and orbits, over the supraorbital ridges, the forehead and the cheek bones, suggesting preserved periorbital tissue. The skull discolored to a pronounced yellow after a few days' exposure to the air. The cephalic index, taken with improvised instruments, was about 91. Cyst 5 contained only black dirt, a few unrelated sherds and a very crude pierced stone pendant, with two holes drilled in it to represent eyes; the pendant is 1.4 inches [3.6 cm] long and of a dark brown, unpolished stone.

The back wall of Temple E-II, immediately south of the altar, was pierced by a rectangular shaft at the floor level. This was approximately one foot square [9 square cm] and must have served as a drain or ventilator. The doorway leading from the central room into the south room appeared to have been sealed. Two large stones formed a kind of threshold which had been plastered over on the side of the central room but not on the side of the south room. Moreover, 2 inches [5.1 cm] of black loam was found on the floor of the south room, but in neither of the other two; from this it might be inferred that after the south wall fell and before this black loam was deposited by decaying vegetation, the walling up of the doorway to protect the central room and altar was undertaken rather than the restoration of the whole south wall. If this hypothesis is correct, it

would indicate that the Maya utilized these temples even after they had started to disintegrate.

Temple E-III, the southernmost of this group of three temples, differs from the others in that it faces W 7 degrees 42' N, making an angle of 7 degrees 39' with the other two. The platform under it, at least on the north side, is parallel to the south side of Temple E-II. The south side of E-III is entirely fallen. In general, the ground plan of Temple E-III duplicates that of Temple E-I, except that the front edge of the altar has no step cut into it. Three cysts were found in Temple E-III. One was in the altar against the back wall of the temple, Cyst 3, and contained a barrel-shaped jar of ordinary ware with a flat, rimmed cover, the whole being 4.4 inches [11.2 cm] high and 4.8 inches [12.2 cm] in diameter. The jar contained an archaic mudstone figurine, sitting on a little heap of dust, with its face to the north. The figurine is extremely crude and represents a person squatting with the arms at the sides of the body, the hands folded over the knees. The eyes, rectangular in outline, are marked off by grooves. When found, the figurine showed many traces of vermilion paint.

The next cyst, 4, was found in the floor south of the altar. It contained two flat dishes of red ware with flaring rims, about 3.75 inches [9.5 cm] deep and 11.25 inches [28.6 cm] in diameter at the rim, the upper one inverted over the bottom one. These contained a cranium complete with the atlas, the axis and the first cervical vertebra; the sutures of the skull were unclosed. On both right and left sides of both upper and lower jaws, the second and third molars had erupted, but the deciduous first molars had not yet been pushed out; all of the teeth were absolutely unworn. It was impossible to determine the sex of the individual. As with the skull from Cyst 6, the frontal region was covered with a friable brown coating; unfortunately the condition of this skull was such that it fell to pieces, even before it could be removed to camp.

The last cyst, 7, was found in the doorway between the outer and inner rooms of Temple E-III. It contained two dishes similar to those already described as containing skulls, but broken. Fragments of bone, unidentifiable but no teeth, were found inside. The lower pot differed from the others in that it had four sets of two perforations midway between the rim and bottom.

Excavation of the base of the substructure mound beneath Temples E-I, E-II, and E-III showed that it was terraced, the terraces being steep and shallow. The main stairway, probably balustraded, was set back 2 feet 2.5 inches [67 cm] from the front of the mound. Stelae 18 and 19 were cleared and it was noted that both are set in the ground obliquely; there was no evidence to show that this was not done intentionally. The altars in front of these two stelae were cleared,

and they were found to be supported on a tripod formed of three large, roughly rounded boulders. Excavations were extended in an effort to determine the exact position occupied by Stela E-I before its fall, and a hole piercing three layers of plaza pavement and ending at a fourth was found 31 feet 5 inches [9.5 m] south of Stela 19; the measured distance between Stelae 18 and 19 being 30 feet [9.1 m], this position for Stela E-I was assumed to be the correct one.

As soon as the progress of the excavations permitted, angular measurements were taken with a theodolite, reading only to tenths of degrees. The directions were determined with the theodolite set up 14.5 inches [36.8 cm] to the east of the center line of Stela 20, a position not impossible for an observer to assume, if the group really served as a solar observatory. Markers were then set up on the midlines of the entrances of the inner doorways in Temples E-I, E-II and E-III. These points were chosen for two reasons: 1. they could be determined exactly, an advantage not offered by many other points; and 2. they stood at the approximate centers of buildings, the exact outside dimensions of which, owing to the total destruction of all north and south exterior walls, must always remain conjectural.

In considering the elements of this group which may have composed a solar observatory, that is, Stelae 19 and 20 and Temples E-I, E-II, E-III, and E-VII, it is necessary to consider the geographic position of Uaxactún. This was determined in 1923 as being Lat. 17 degrees 23.8' N and Long. 89 degrees 38.4' W from Greenwich.⁵ The correction for the magnetic declination of the compass for 1927 is 7 degrees 12' E,⁶ and the amplitudes for sunrise are as follows:

Table 28.3.1. Amplitudes for Sunrise, Uaxactún.

True Horizon	Visible Horizon	Extreme Values During Year
24.6	24.4	North of east on June 22
24.6	24.9	South of east on December 22

The true astronomic directions are as follows. A correction of 7 degrees 12' east, for the magnetic declination of the compass in this region in 1927 as noted above, has been used throughout.

These figures show variations from the figures given by Frans Blom [Chapter 28.1], whose preliminary observations were made with a Brunton Pocket Compass and without excavation. The chief differences lie in the sights from Stela 20 to Stelae 19 and 18, given by Mr. Blom as true East and N 76 degrees E, respectively.⁷ His bearing to Stela E-I may be thrown out entirely, as its position without excavation could only be conjectured. Mr. Blom states that the angle between Stela 18 and Stela 19 (as taken from Stela 20) is 14 degrees; this is approximately correct, but he places Stela 18 1 degree 12' and Stela 19 1 degree 45' too far north. The angular difference between the two centers is actually 14 degrees 33'.

As a check, angles of 24.4 degrees to the north of, and 24.9 degrees to the south of the true east-west line were measured off in the field from Stela 20. These lines are labeled *a n* (amplitude north) and *a s* (amplitude south) on the accompanying diagram. Upon completion of the plan of Group E on paper, similar angles for the amplitude of the Sun were laid off from the point T, at the top of the stairway on Pyramid E-VII. These angles as extended are indicated by the lines *A N* and *A S* on the diagram. It is greatly to be regretted that Temples E-I and E-III are so very badly fallen, for an observer standing on the stairway of Pyramid E-VII could so change the location of his eye by ascending or descending the steps as to cause the amplitudes of the Sun to fall anywhere between *A N* and *a n*, and *A S* and *a s*. This fact not only gives a great deal of leeway for the location of the point sighted upon from Pyramid E-VII, but it allows the observer to mount from the plaza level to a point as high as 35 feet [10.7 m] in the air (plus his own height), a distinct advantage in making a sight in relation to a temple, the platform of which already rests on a substructure mound 15 feet [4.6 m] high. Obviously, no horizon sight can be made from Stela 20 with this mound looming in the way. Furthermore, since the north wall of Temple E-I and the south wall of Temple E-III must fall somewhere between the lines *A N* and *a n*, and *A S* and *a s*, respectively, it is self-evident that from some position on the midline of the stairway of Pyramid E-VII an observer would see the sun rise on the summer and the winter solstices in

Table 28.3.2. Variation in Astronomical Observations, Uaxactún.

From Stela 20 to	True Bearing	Degrees of Arc From True East	Amplitudes of Sun at Uaxactún
Center of doorway Temple E-II	S89 degrees 03'E	0 degrees 57'S	Equinoxes
North Jamb Doorway Temple E-II	True east	0	
Stela 19 (center)	S88 degrees 15'E	1 degree 45'S	
Stela E I (hole)	S74 degrees 18'E	15 degrees 42'S	24.9 degrees on December 22
Center of Doorway Temple E-III	N65 degrees 18'E	24 degrees 42'N	
Stela 18 (center)	N77 degrees 12'E	12 degrees 48'N	
Center of Doorway, Temple E-I	N68 degrees 00'E	22 degrees 57'N	24.4 degrees on June 22

relation to these temples. If he placed his eye 15 feet [4.6 m] above the plaza level (that is, level with the top of the eastern substructure), the amplitudes of the Sun would fall along the lines $a'n'$ and $a's'$. From this same point the directions north 83 degrees east and south 83 degrees east were laid off (that is, 7 degrees north and south of the true east-west line). These directions mark the dates of sunrise on April 6 and September 6, and March 3 and October 10 respectively, which are about 17 days before or after the dates of the equinoxes.⁸ It is interesting to note how closely they approximate the outlines of Temple E-II.

If we compare these dates with the dates on the three standing stelae in Group E, we see a close approximation as regards the April dates.⁹

Table 28.3.3. Calendrical Decipherments, Uaxactún.

Stela 19	8.16.0.0.0	3 Ahau	8 Kankin	April 5, 97 AD.
Stela 18	8.16.0.0.0	3 Ahau	8 Kankin	April 5, 97 AD
Stela 20	9. 3.0.0.0	2 Ahau	18 Muan	April 3, 235 AD ¹⁰

The 1927 expedition is deeply indebted to many individuals for their courtesy and assistance, chief among whom are Mr. and Mrs. P. W. Shufeldt, Mr. C. O. Taylor, and Mr. Robert Masson of Belize; Dr. and Mrs. Patterson of El Cayo; Sr. Lic. Don Antonio Villacorta, Sr. Ing. Don Fernando Cruz, Sr. Dr. Don Federico Mora, Sr. Lie. Don Virgilio Beteta, Sr. Don Carlos Luna, Mr. James Roach and Mr. David Davidson of Guatemala, and to Mr. G. P. Chittenden of the United Fruit Company, through whom many courtesies were extended by the Guatemala Division. Mr. Ricketson is personally indebted to the Department of Terrestrial Magnetism of the Carnegie Institution of Washington for supplying him the magnetic and astronomic data.

NOTES

1. Incorrectly reported in [Chapter 28.1] as crowned with the remains of a temple facing south.
2. All directions are true or astronomic.
3. Compare the shrines in the Palenque temples.
4. Dr. Grover Allen can identify the following: Yucatecan leaf-nosed bat, short-tailed bat; Yucatán cotton rat, the rice rat?
5. Incorrectly given in [Chapter 28.1] as Lat. 17 degrees 23' 8" N and Long. 89 degrees 38' 4" W.
6. Information supplied by the Department of Terrestrial Magnetism, Carnegie Institution of Washington.
7. Two errors in [Chapter 28.1] should be corrected here, besides that of the geographic position of Uaxactún, already noted. [The] following sentence "We see that the lines of sight from Stela 20 to Stela 18 and F.a. [misprint for E-I] are 24 degrees north and south of the true east, coinciding with the two extremes at which the sun rises during

the year " should read " We see that the lines of sight from Stela 20 to Temples E-I and E-III are 24 degrees north and south of the true east."

8. Information supplied by the Department of Terrestrial Magnetism, Carnegie Institution of Washington by letter of August 13, 1927, no. F 1.

9. In order to determine if the discrepancy between April 6 (as given by the direction N83 degrees E) and April 5 (as given on Stelae 18 and 19) were significant, the direction to the probable location of the northwest corner of Temple E-II was taken. This is N 85 degrees 10' E a difference of 2 degrees 10', too much to account for only one day. A tentative explanation for this discrepancy of one day has been offered by the Department of Terrestrial Magnetism in the fact that the difference between 97 AD and 235 AD is 138 years, that is, an interval for which the excess of 365.25 days above a solar year would amount to a trifle over one day (one day in 128 years, to be more exact.)

10. Maya dates deciphered by Dr. S. G. Morley; equivalents in. Christian chronology according to the correlation proposed by Dr. H. J. Spinden.

28.4.

OLIVER G. RICKETSON

Report on the Uaxactún Project

YB 27:307–312, 1928

In conformity with the contract granted by the Government of Guatemala to the Carnegie Institution of Washington for the excavation of the ruins at Uaxactún [Chapters 28.1 and 28.2], the third season was inaugurated early in January 1928. The members of the field expedition consisted of Monroe Amsden, in charge, A. Ledyard Smith and Harry E. D. Pollock, assistants.

Immediately upon arrival in camp on February 1, all hands were set to work completing and expanding the buildings erected in 1926 and 1927, clearing the year's growth, and beginning the construction of a dam across a nearby arroyo to provide a future water supply.

On Sunday, February 26, Messrs. Smith and Pollock left to visit a new ruin reported about 5 miles [8.1 km] northeast of Juventud Station. A sketch map was made, showing extensive constructions around a main central mound 80 feet [24.4 m] high. Two stelae, uncarved, were found along the north border of the main plaza. The ruin was named El Paraiso.¹ As the party was returning from this ruin to Juventud, in as

nearly straight a line as possible, it encountered a peculiar wall, 40 feet [12.2 m] long, 2 feet [61 cm] high, and 10 feet [3.1 m] thick. No other walls adjoined it; it was apparently, not hollow, nor could it have served as a roof-comb.² Its function could not be ascertained without extensive excavation, for which there was no time.

On Monday, February 27, ten workmen started clearing Group E of the annual growth, as well as an area to the west of Pyramid E-VII to make easier access to a new dump. On February 29, excavation was started on the northwest corner of Pyramid E-VII, where some of the primary construction, had been exposed the previous season.

The chief effort of the 1928 field season was expended in removing the outer shell of secondary rubble from Pyramid E-VII, in order to expose the primary construction beneath, which will be referred to hereinafter as Pyramid E-VII sub. In this excavation the extremely poor construction of the secondary pyramid made it impossible to obtain very detailed information, though it was ascertained that stairways had ascended to within 20 feet [6.1 m] of the top on all four sides. The apex of the pyramid was the latest addition; inasmuch as six horizontal strata of compact dirt and very small stones were found in this apex, it may well be that each stratum represents an original capping to the whole. These strata were each 6 inches [15.2 cm] deep and occurred at the following levels, numbering from the top down and measuring the height from the plaza floor: 1, 45 feet [13.7 m]; 2, 42 feet [12.8 m]; 3, 41 feet [12.5 m]; 4, 39 feet [11.9 m]; 5, 36 feet [11 m]; 6, 32.5 feet [9.9 m]. The greatest height of the pyramid, ascertained the previous years, was 50 feet [15.2 m].

In the coarse rubble forming the hearting of the apex three cysts were found: Cyst 10, lying on the fourth floor, at the 39 foot [11.9 m] level; Cyst 11, on the fifth floor, at the 36 foot [11 m] level; and Cyst 12 lying between the fourth and fifth floors, about 1 foot [31 cm] higher than Cyst 11.

Cyst 10 was a rectangular grave of large, cut, untrimmed stones and mud. Its long axis extended east and west. It contained the headless skeleton of a female, whose age was estimated as 25 years. The skeleton lay fully extended, face down, the feet toward the west, the right arm extended beneath the pelvis, the left arm flexed with the hand under the left shoulder. The grave itself was 20 inches [50.8 cm] wide and 5 feet 6 inches [1.7 m] long. The west end of the grave was 5 feet 6 inches [1.7 m] from the nearest point on the outside face of the pyramid, the east end 4 feet [1.2 m], and the south side 8 feet [2.4 m]. At this level the summit of the pyramid measured approximately 25 feet [7.6 m] north and south and 15 feet [4.6 m] east and west. The grave was closed with a layer of very

small stones. There was a space of 6 inches [15.2 cm] between the first vertebra and the east wall of the grave.

Cyst 11 lay just north of Cyst 10, though at a lower level. It was semicircular in shape, with the flattened base of the semi-circle to the west and in line with the west end of Cyst 10, and the apex of the curve pointing to the east. It measured 3 feet [91 cm] along the base, north to south, and 2.4 feet [73 cm] along the mid-line, east to west. It contained six pots, three plain redware dishes with flaring rims and three plain brown ware cylindrical pots with covers. These were similar to the dishes and pots found in Cysts 1 to 9 in Temples E-I, E-II, and E-III the previous season. Large stones were placed in this cyst to prevent the weight of the superimposed earth from crushing the vessels. The floor of the cyst was formed of a compact stratum of mud and small stones.

The redware dishes (1, 2, 3) were stacked in the extreme northwest corner, the two lower dishes one inside the other and the third dish, inverted so that it lay rim to rim with the inner bottom one. All were 6.5 inches [16.5 cm] in diameter at the top, 4.5 inches [11.4 cm] at the bottom, and 1.75 inches [4.5 cm] deep.

The brown ware cylindrical pots (nos. 4, 5, 6) were placed in a line running diagonally across the cyst, that is, toward the southeast, from the redware dishes. No. 4, lying nearest nos. 1, 2 and 3, measured 5.5 inches [14 cm] in diameter and 5.5 inches [14 cm] in height; no. 5, next to 4, was 5.25 inches [13.3 cm] in diameter and 5.5 inches in height; and no. 6, next to 5, was 5.5 inches [14 cm] in diameter and 5.25 inches [13.3 cm] in height.

Of the redware dishes, the upper (no. 3) and the lower (no. 1) were cracked; no. 2 was intact. Of the brown ware pots, no. 4 had the cover broken in excavation; it contained two (jade ?) beads, one with red paint on it, and flakes of some silvery colored material; no. 5 was intact and also contained silvery colored material and some partially dried brown gummy material; no. 6, also intact, contained both the silvery and the, brown material (some of the latter still adhering to the sides) and seeds resembling those of the squash.

Cyst 12, like Cyst 11, was semi-circular and occupied the same relative position on the south side of Cyst 10 that Cyst 11 did on the north. It measured 3 feet both along the base line, from north to south, and along the mid-line, from east to west. It contained seven pieces of pottery in all, two plain redware dishes with flaring rims, the top one (no. 1) inverted over the bottom one (no. 2), and five plain brownish redware cylindrical pots with covers (nos. 3, 4, 5, 6, 7). The dishes were placed along the northeast arc of the cyst (at "eleven o'clock," in the parlance of target shooting), and the cylindrical pots were placed irregularly in the central east and west zone from base to apex. As in

Cyst 11, stones placed in the open space prevented the earth above from crushing the pottery.

The two redware dishes were 5 to 5.25 inches [12.7–13.3 cm] at the base and 9.5 inches [24.1 cm] in diameter at the rim, and 2.25 inches [5.7 cm] and 3 inches [7.6 cm] in height. Both were cracked, and in the space between them were two snake's eggs, small pieces of charcoal and a sandy substance with a red-dish tinge. The pots measured from 5 to 6 inches [12.7–15.2 cm] in diameter and 4.75 to 5 inches [12.1–12.7 cm] in height. They were intact and contained variously shells, seeds, a silvery substance, partially dried gummy material and a reddish material on the bottom. No. 7 also, contained two pieces of obsidian, and between nos. 3 and 4 was found an obsidian lancet, measuring 6.5 inches [16.5 cm] by 0.5 inch [1.3 cm], extremely sharp and well made.

Two other redware dishes with flaring rims were found in secondary rubble at the level of the seventh terrace, just along the north balustrade of the secondary stairway. This cache is called Cyst 9; though the dishes were imbedded in solid mud. The top dish was inverted over the bottom one, but nothing was contained between them except three stones, each measured 10 inches [25.4 cm] in diameter at the rim, 6.5 inches [16.5 cm] in diameter at the base, and 2 inches [5.1 cm] deep.

In the new clearing made for the laborers' camp, an olla and pitcher of coarse brown ware, of more recent manufacture, were found lying on the ground. The olla measured 8 inches [20.3 cm] from the rim to the tip of its conical bottom; its greatest diameter, 11.5 inches [29.2 cm], occurred just below the very slight constriction under the everted lip. The pitcher was 7.5 inches [19.1 cm] in depth and the same in diameter.

After the removal of the secondary rubble from Pyramid E-VII (except from the southwest corner, purposely left covered as a control), Pyramid E-VII sub was exposed practically in its entirety. It consists of a terraced platform, with seven different levels. It measures 25 feet [7.6 m] in height, 79 feet [24.1 m] north and south, and 76 feet [23.2 m] east and west at the plaza level. Four main stairways, each composed of three flights of six steps each, mount the centers of the four sides from the base of the pyramid to the level of the fifth terrace. From this level one more flight of five concavely curved steps mounts, on the east side only, to the level of the sixth terrace, the posterior two-thirds of which is raised about one foot [31 cm] to form a low platform called the seventh terrace. The stairway on the east side, which faces the plaza and is the main façade of the structure, is bounded by six large stucco masks, three on either side, and the stairways on the other three sides are bounded by four similar masks each, two on either side. There are, therefore, 18 masks

on the whole pyramid; these have been numbered 1 to 18 according to the following plan: nos. 1 to 8 are the masks of the lowest tier, beginning with the mask south of the East Stairway and passing around the pyramid counterclockwise to no. 8 on the east side of the South Stairway; nos. 9 to 16 are the masks of the tier above, beginning again with the mask on the south side of the East Stairway just above no. 1 and passing around the pyramid counterclockwise to no. 16 just above no. 8; nos. 17 and 18 are the masks of the third tier and lie on the south and north sides, respectively, of the five concavely curved steps which lead from the fifth terrace to the sixth and seventh terraces on the east side only.

Masks no. 2 and no. 10 were uncovered in 1927 and the description of no. 10 already given [Chapter 28.3] will roughly suffice for all the masks in the second tier. Although no two masks are identical, all are strikingly similar in the following respects:

1. Each mask is, roughly, 8 feet [2.4 m] square.
2. All are made of lime stucco, over a built-up stone core.
3. All are of good workmanship, in rather low relief, and primitive rather than sophisticated in treatment.
4. The mouths of all appear as narrow, sunken slits from which depend two lateral, outward-curling fangs, and one central, more ornate, roughly heart-shaped appendage which might be tooth or tongue.
5. All the noses have a specialized decoration, either a tapered roll ornament hanging in a catenary curve between the eyes, or three parallel horizontal bands with gently rounded edges.
6. All have conventionalized head-dresses, perhaps representing feathers; the elements of which are flowing scrolls, untapered and ending in curls with the characteristic Maya blunt tip.
7. The expression of each mask is grotesque, ferocious.
8. The ears, depicted as without ear-plugs, extend the full height of the mask, and are in every case extremely conventionalized.

The lowest tier of masks, nos. 1 to 8, are even more difficult to describe for they are in such bad condition that their original character is scarcely recognizable. They suggest nothing so much as highly conventionalized serpents' heads, but this fact runs counter to the hypothesis that the cult of Kukulcan or the Feathered Serpent was a late Aztec or Toltec influence among the Maya. It is hoped that better preserved and less debatable examples may turn up in farther excavation. These masks are approximately 8 feet [2.4 m] wide and 6.75 feet [2.1 m] high. About 16 inches [40.6 cm] of the top extends above the level of the fourth terrace. The upper half of each mask is composed of conventionalized scrolls, one of which curls in such a way on either side as to suggest eyes. Across the center

of the mask is a horizontal slit obviously representing a mouth, and in it are pointed teeth, but the lateral pendant curling fangs associated with the Feathered Serpent in northern Yucatán are absent. Below the mouth, in the center, hangs an oblong appendage upon which is shown in slight relief a tongue with two outcurling, scrolls; this design, suggesting the bifurcated tongue of a snake, is often seen in northern Yucatán in connection with representations of the Feathered Serpent. The lowest third of the mask, countersunk deeper than those portions described above appears to represent the throat. It shows a dentate design in two horizontal rows, the points down, much like triangular tipped shingles on a house, and this has been interpreted as a crude representation of feathers or scales; this, part of the design certainly does not represent teeth.

The two masks bounding the East Stairway at the level of the fifth terrace, nos. 17 and 18, are smaller and more ornate. They measure 5.6 feet [1.7 m] and 6.6 feet [2 m] in width, respectively, and 5 feet [1.5 m] in height. Each represents a human face with a large, out-curling fang hanging from either side of the mouth. The face is framed by a scroll head-dress above and ears with large ear-plugs on either side. The nose, decorated with a tapered roll hanging in a catenary curve, is greatly exaggerated in both masks, and extends down-in front of and beyond the mouth. The foreheads of both are decorated with a plain plaque in the center. Both these masks show traces of red paint. In this connection it may be noted that Mask no. 10 had a red line, 3 inches [7.6 cm] long and 0.125 inch [0.3 cm] wide, on the left cheek, but the rest of the face had apparently never been painted.

Besides the main stairways facing the four cardinal points on Pyramid E-VII sub, which is accurately located in respect to the true or astronomic points of the compass, there are decorative steps on the various terrace levels below the fifth. They occur just outside the masks (except in the case of nos. 17 and 18, which are above the fifth terrace), and are approximately 4 feet [1.2 m] wide. Compared to the main stairways, which, are 9 to 10 feet [2.7–3.1 m] wide, they seem very small and could have served no essential function, other than to give access to all parts of the masks' faces. The first three flights lead from terrace to terrace, these three terraces being but 3 feet [91 cm] high each; the fourth and topmost flight ascends only 4 feet [1.2 m] of the 9 foot [2.7 m] high fourth terrace, ending against sheer wall too high to climb. The first three terraces and the fifth have simple cornices; the fourth terrace has both a plain basal cornice, 18 inches [45.7 cm] high; and a band, 2 feet [61 cm] wide, raised in relief 2 feet [61 cm] down from the top of the terrace.

The measurements of Pyramid E-VII sub at plaza level have already, been given. The four main stairways which run to the top of the fifth terrace give access to an area 33 feet [10.1 m] north and south, 20 feet [6.1 m] east and west, on which is located (3 feet [91 cm] back from the top of the East Stairway) a low mound or platform of two levels which form the sixth and seventh terraces. This platform is 4.5 feet [1.4 m] high in front and 5.5 feet [1.7 m] high in back the step-up occurring 3.5 feet [1.1 m] from the top of the concavely curved flight of five steps, bounded by masks nos. 17 and 18, which already have been described. Four cysts were found in this platform, Cysts d and e on the lower level near the front, and Cysts f and g on the upper level near the back. No objects were found in these cysts and Cyst f is typical of all four. This cyst was a circular hole, 14 inches [35.6 cm] in diameter and 52 inches [132.1 cm] in depth. Its outlines were sharply definable. A hole 25 inches [63.5 cm] in diameter had been dug through the 11 inch [27.9 cm] thick black flooring, and Cyst f had been sunk at the southern side of this; 5 inches [12.7 cm] to the north lay a very small cyst, f', only 6 inches [15.2 cm] in diameter and 2 feet deep. Cyst f contained about a foot [31 cm] of brown mold and some charcoal in the bottom, which suggests the possibility that these four cysts, each with a little cyst accompanying it, served as post holes for the timbers of a wooden structure on the top of the pyramid. These cysts had been sealed with white plaster at floor level, presumably after the posts had been removed and the secondary pyramid constructed.

Toward the close of the field season, Dr. Kidder and Dr. Morley, and Dr. G. C. Vaillant of the American Museum of Natural History, New York, visited the ruins, Dr. Vaillant coming as ceramic expert upon the invitation of the Carnegie Institution of Washington.

Although the excavation of Pyramid E-VII sub had occupied most of the field season and brought to light for the first time a new type of early Old Empire temple hitherto unknown, unique in style and with interesting variants of the usual Maya features, a most important discovery during the season is due to the work of Dr. Vaillant who sank exploratory trenches at two positions in the plaza and ably interpreted the information gained thereby.

The first of these trenches (Trench no. 1) was sunk at right angles to the east face of Pyramid E-VII sub, a few feet south of its northeast corner. Trench no. 2 was then dug at right angles to no. 1, due south to Stela 20. A third trench, Trench no. 3, was dug on the east side of the plaza, in front of the space between Temples E-I and E-II and north of Stela 18. Conditions here were almost identical with those found in Trenches nos. 1 and 2; floors presumably corresponding to, those already found in nos. 1 and 2 were observed to run be-

neath the substructure of Temples E-I, E-II and E-III, indicating the probable presence below the substructure of an earlier building, perhaps synchronous with Pyramid E-VII sub.

The 1928 expedition is again indebted to the following persons for their many courtesies: to Mr. and Mrs. P. W. Shufeldt and Mr. C. O. Taylor of Belize; to Mr. Robert Masson, of His Majesty's Customs, Belize, and to Mr. G. P. Chittenden of the United Fruit Company. Mr. Ricketson, on temporary leave of absence from the field, is personally indebted to the members of the field staff and to Dr. Vaillant for their efforts in obtaining the material for this report, and for their cooperation in its preparation.

NOTES

1. It is located on P. W. Shufeldt and Co.'s map near a chicle camp of this name.
2. Compare the "wall" reported in [Chapter 28.3].

GEORGE C. VAILLANT

Report on the Excavations in the Plaza of Group E at Uaxactún

YB 27:313–317, 1928

A feature of the season's excavations at Uaxactún was the discovery of conditions favorable for an examination of the relationships between the stelae and the structures at Group E. The close of the season prevented a definite interpretation of the data gained, but the historical implications are of considerable import.

The presence of Stela 20 and the primary and secondary pyramids of E-VII gave every promise of fruitful correlation and research. The first step was to find bottom, and from this preliminary pit (Trench 1) trenches, were run west to the primary pyramid and south to Stela 20 (Trench 2). It was possible, therefore, to observe from two sides the stratification. Later, eastward by 150 feet [45.7 m] across the plaza at Stela 19, a trench (Trench 3) was dropped to study the relationships at that point. Unfortunately time was lacking to join by trenching the operations at Stela 20 and Stela 19.

The conditions in Trench 1 comprised a series of four floors overlying a layer of perhaps redeposited refuse. This deposit rested on a fill of rocks mingled

Figure 28.5.1. Uaxactún, excavations in the plaza of Group E. *a.* Trench 3 on east side of plaza near Stela 18; *b.* Trenches 1 and 2 on west side of plaza near Stela 20.

with charcoal, potsherds and, vegetal debris. Underneath this layer stretched a thin stratum of what appeared to be humus, and excavation was stopped after producing pure clay for a foot. In the southwest corner of this trench a pit was dug through the humus into the clay containing ash, burned kernels and burned rocks. This deposit represented, doubtless, a firepit. In Trench 2, excavations were carried only a short distance into the rock fill. Between the fill and the base of the floor occurred the very fragmentary remains of a young adult burial, with two jade beads near the neck.

Beginning from the bottom of the series of strata in Trench 2, we observe, from the section in the accompanying figure, that the original occupation surface was thinly covered with humus on the clay subsoil. Above this is a thick layer of stones mixed with sherds and charcoal. This section looks more like a leveling process in which rubbish layers were spread out and redeposited, than the natural accretion of human refuse. Yet, curiously, above this stone layer the earth is soft again but without the laminations and lenses of ash, vegetal and other debris that are characteristic of most deep rubbish beds.

Resting directly on this soft bed is the primary pyramid, E-VII sub, and extending from its base is the hard white plaster Floor a-a. Directly above, and at times indistinguishable from Floor a-a, is Floor b-b. This latter surface seems to be in the nature of an element of repair and not part of any extensive system of architectural change or addition.

Floor c-c seems to be the product of a plan of alteration. The original pyramid, as described in the preceding report of O. G. Ricketson, Jr., rises in corniced

steps. Unfortunately our section is taken through a different part of the building, i. e. through the balustrade, and does not show this condition. Floor c-c, however, is carried out from the base of the cornice, so that this latter architectural feature disappears. This willingness to sacrifice to the new floor level a significant architectural feature must signify some important external change, perhaps the construction of additional buildings in another part of the plaza.

Floor d-d, the topmost surface, is so badly destroyed by the action of roots and trees that only a vestige remains around the base of Stela 20. However, since the first three floors we have considered belong to the primary pyramid, this fourth must be associated with the covering or secondary pyramid. Stela 20, of early date, 9.3.0.0.0, must be associated with this latest floor, since a cup-shaped hole was excavated through the lower floors to receive the shank of the stela. The lower edge of the frame of the sculptured panel was a little' above Floor d-d.

Across the plaza, 150 feet [45.7 m] to the east, Stela 18 is situated immediately in front of the long substructure on which rest Temples E-I, E-II, and E-III. A trench (Trench 3) was dropped to the north of the monument to find out the relationships of substructures, floors and this stela, which bears the very early date of 8.16.0.0.0. The conditions in the main are very similar to those in Trenches 1 and 2 on the opposite side of this plaza.

In Trench 3, the bottom layer is of clay with a thin layer of humus containing a very few sherds. The next stratum is composed of stones mixed with debris, and from this layer came most of the sherds. At the west end of the trench, a thin plaster floor, a'-a', resting on this level, was exposed. There was not, however, any trace of walls. Perhaps they had been of wattle-work.

Directly above a'-a' is a fill of the same character as below it—dirt and stone mixed. East of a'-a' the upper fill is of pure rock with no dirt in the interstices. In the accompanying figure this condition has been labeled "loose fill"; the state of the lower strata, where the interstices are filled with soil, is entitled "tight fill."

Above this last-mentioned stratum is a thick solid floor a-a, which, as in Trenches 1 and 2, is of plaster, lime and the residue from burning lime. Directly over this floor is another equally hard, b-b. Both these floors pass under the eastern substructure of the plaza of Group E. Up to this point the conditions are practically' homologous with those in Trenches 1' and Floor c-c is thicker than the equivalent surface in the western trenches comprising a foot and a half [45 cm] of material. Directly under the west face of the substructure of Temples E-I to III, there is a stone which may represent a coping. If this be so, there is a strong presumption that the development of the E group was out and east from the primary pyramid of E-VII.

Floor d-d is clearly represented in Trench 3 by a surface coped with stone around Stela 18. This floor is definitely associated with the substructure of Temples E-I to III, since the lower floors all pass, beneath it. Stela 18 is set in a cup-shaped depression, and is wedged firm by small stones. The socket extends through Floor c-c, to a little above Floor b-b. It is not so deeply set as Stela 20. Another point is that while Stela 20 is set with its long axis parallel to the secondary pyramid of E-VII, Stela 18 is slightly askew to the substructure with which it now corresponds.

Levels were not taken to compare the floors, but in the, stratigraphical complexes of Trenches 1-2 and Trench 3, the number of surfaces is the same. The greater thickness of the floors in Trench 3, taking the surface a-a as a fixed level for measurement, is merely an increase of between 6 inches [15.2 cm] and a foot [30.5 cm] in a distance of a little over 150 feet [45.7 m]. While a linking of Trenches 1 and 2 with Trench 3 would give more complete data, the correspondence is close enough to permit the drawing of certain conclusions from the data at hand.

Of the original contour of the low hill upon which Group E is situated, we have as yet no information. Yet the first occupants must have lived directly on its surface without making any great effort to adjust its probable irregularities, by leveling or terracing.

As time went on, however, and judging from the depth of the debris, it was a considerable period, there must have been some rude attempt at leveling, as the presence of so many stones in, the debris attest. But in this stone layer there are also many sherds. This combination seems to indicate a shoveling of debris from the top of the hill to level off the surface. Substance is added to this hypothesis, by the presence of Floor a'-a' in Trench 3.

However, after this leveling, occupation must have continued for some time, since in Trenches 1-2 we find pure debris and a skeleton above the stone fill. It would facilitate interpretation of ground conditions if we knew whether it was a Maya custom to bury in rubbish beds which were contemporaneously accumulating. It is not so easy to account for the fill above, Floor a'-a', which contains stones.

Pottery found in the levels below the a-a floor system consists of wares with yellow-white, red, brown to black, and gray slips. The first three wares have a flaky base clay, but the slip is hard. The Grey Ware is porous and powdery, and is used for storage vessels. The Yellow-White Ware is rarely painted in red, but sometimes a red secondary slip is coated over it. The Brown-Black Ware is decorated mainly by incision and by modeling. The shapes for the red and the Yellow-White wares are low squat dishes with concave bottoms, or deeper vessels, almost conical. The shapes in

brown-black wares are globular bowls, ollas of small size, and cylindrical vessels. Associated with these pot forms are figurines with modeled bodies; in technique the faces are on the border line, between molding and modeling. In expression some heads begin to show Maya features, although there is a "feeling" of the plastic of the unspecialized cultures of Middle America (the so-called Archaic). An owl-whistle was also found. Summing this material up, it seems to be in pot-form, non-Maya, but, in the plastic art, just emerging into that type called Maya. While not resembling it in any but the most general way, the nearest ceramic group is the material found by Dr. Gamio at the Finca Arenal just outside Guatemala City.

Directly over this lower level material, stretches the Floor a-a which is associated with Pyramid E-VII sub. From the preceding report, it will be seen that this structure is not in the Petén tradition of steeply rising slopes broken by narrow terraces. While the masks give the structure a Maya flavor, the stepped profile recalls the pyramid types of the highlands of Guatemala, although it seems improbable that there is contemporaneity between the latter and this undoubtedly early building. Possibly E-VII sub belongs to a common ancestral type.

It will be of the greatest interest to find other structures in Group E of the same period as E-VII sub. The conditions in Trench 3 seem to make such a find likely, for, not only did the floors pass under the substructure of Temples E-I to III, but there is also a formal foundation of dry stone (loose fill), that suggests a considerable enlargement of the original hill top. Floor b-b was laid apparently as a repair surface, but Floor c-c seems to be a connective floor, for the rise in level is more than necessary for the needs of repair. The bringing of Floor c-c up to the cornice level of E-VII sub tends to confirm this assumption. Not enough material was found to indicate the ceramic styles of Pyramid E-VII sub, or the Floor c-c period, for the rubbish deposits of these horizons were not encountered.

As explained above, Floor d-d is the surface associated with E-VII, the substructure of E-I to III, and Stelae 18 and 20. But there is a difference of 138 years in time between these two stelae. At the present we can not say which of the stelae is contemporary with Floor d-d, nor can we show that neither is contemporary with the architecture, having been removed from some other locality and re-erected here. It is significant that Stelae 18 and 19 are badly aligned with the substructure behind them, hinting perhaps at the presence of an earlier structure, but the juncture of Floor d-d with this substructure militates against this assumption. In the masonry forming Pyramid E-VII sub, a fragment of a bowl was found that resembles so closely as to be stylistically identical with a vessel found in the sec-

ond of four groups of burials at the stratified, apparently Old Empire pyramid of Holmul.

The other pottery in the fill also carries the characteristic style of Holmul pottery comprising vessels with porous base clays, and black or red slips like a lacquer. Storage pottery is of porous friable gray-ware striated on the exterior. In shape, the red and black-ware bowls are composite silhouette rim bowls with broad flanges at the point of unión between the rim and the base sections.

The pottery from Temples E-I, II and III, from a casual inspection, seems different from this style, showing cylindrical legs and an absence of the flange, having some resemblance to the latest ceramic period at Holmul. The small stone idol discovered in the season of 1927 might be assigned to the sub-floor period of Pyramid E-VII, but this classification is conjectural.

In short, then, at the E Group at Uaxactún, there was a long period of occupation, punctuated not only by architectural changes in structure, ground-plan and level, but also by changes in the major and minor-arts. A complete series of trenches would yield that which the archaeology of the Maya most needs a chronology based on material culture and possibly even a correlation between the stelae which record absolute time and the sequence of the material culture. We have then the following phases:

1. Original occupation.
2. Floor a'-a' and expansion of the town of the first inhabitants.
- 2a. Possible abandonment of this town, as seen by the burial in Trench 2.
3. Construction of Pyramid E-VII sub and Floors a-a and b-b.
4. Expansion of site of E-VII sub people as seen by Floor c-c.
5. Construction of Pyramid E-VII sub, and the substructure of Temples E-I to III. Insertion of stelae. Stela 18 and 19 may represent a period intermediate between 4 and 5, and people of the epoch may have made the pottery in the fill of Pyramid E-VII.
6. Occupation of the people who left their pottery in Temples E-I, E-II and E-III, and who, perhaps, may have built these temples.

The great point raised by this season's excavation is, how high a culture, as Pyramid E-VII sub attests, existed before the erection of stone monuments by the Petén Maya. We may have discovered the origin of "Maya" culture, but we have yet to find the mother-culture of its originators.

OLIVER G. RICKETSON

Report on Miscellaneous Excavations

YB 28:323, 1929

A burial was found in the center room of Structure E-X, lying head to the north, face up, in a shallow grave that been dug through the two lower floors. Two upper floors covered it. The skeleton was that of a male, the skull showing slight occipital flattening. The facial portions had disintegrated; although the mandible was recovered, only 10 teeth were found. The skeleton lay on its back, left arm across the abdomen, the right so flexed that the hand rested on the right clavicle. The pelvic region was filled with ash and charcoal, and from the waist down the body lay more nearly on its right side, the left knee half-flexed and lying over the right. The objects found with the skeleton were all placed around the head; these consisted of four pieces of bone, two shell disks, one shell ring, one annular shell lip-plug with small pits cut on the anterior surface, one whole shell with four perforations, one piece of shell and half a mandible of a carnivorous animal with the end cut off smoothly.

Five pits were dug in Group A, around Temple A-V, Pit 1 to the west, Pit 2 to the north, Pits 3 and 5 to the east and Pit 4 to the south. Pit 1 pierced a floor at 1 foot 6 inches [45.7 cm] and struck blue clay at 4 feet [1.2 m]; Pit 2, 4 feet 6 inches [1.4 m] deep, pierced a floor at 1 foot 4 inches [40.6 cm] and struck marl at 2 feet 6 inches [76.2 cm]; Pit 3, 4 feet [1.2 m] deep, pierced a floor at one foot [31 cm] and struck marl at two feet [60.9 cm]; Pit 4, 3 feet [91.5 cm] deep, encountered no floor and stopped at bedrock; Pit 5, 3 feet 6 inches [106 cm] deep, pierced a floor at 10 inches [25.4 cm] and another at 2 feet 2 inches [66 cm] which overlay 10 inches [25.4 cm] of dirt and limestone, and 6 inches [15.2 cm] of burnt lime, black dirt and small pieces of unburnt lime. Pit 4 yielded a three-legged flat dish of red ware, with rattle legs. Two trenches were dug into the slope north of A-V, to determine whether the apparent talus slope from the artificial retaining wall along the top of the hill had been formed by refuse from the, complex group of buildings above, but this slope was found to be composed of solid limestone under one foot [31 cm] of vegetable humus.

OLIVER G. RICKETSON

Report on the Excavations at Uaxactún

YB 28:316–322, 1929

In conformity with the contract granted by the Government of Guatemala to the Carnegie Institution of Washington for the excavation of the ruins at Uaxactún, the fourth season was inaugurated early in January. The expedition consisted of Oliver Ricketson, Jr., in charge, A. Ledyard Smith, assistant archaeologist, Edith Bayles Ricketson, and Enrique Shufeldt, field assistants.

Although Mr. and Mrs. Ricketson arrived in Belize, British Honduras, on January 9, it was not until February 7 that they, accompanied by Mr. Shufeldt, were able to leave for El Cayo, and the ruins. This delay was due to the chaotic transport conditions prevailing in the Department of Petén, Guatemala, as the result of the cessation of work in that district by the P. W. Shufeldt Co., on which previous expeditions had depended for the transportation of supplies. It was finally necessary for the expedition to purchase ten pack mules, to add to the 10 animals already owned, and to organize its own pack train.

Upon his arrival in El Cayo, Mr. Ricketson called officially upon the Guatemala customs authorities at Fallabon, to present his credentials. The expedition arrived in Uaxactún on February 20, and on February 25, after the necessary clearing of the ruins and repairs to the field headquarters had been completed, the excavations in Group E were resumed.

The season's work may be divided into four parts: 1. Excavations in Group E; 2. An examination of the stela to determine possible relationships between stelae and plaza floors, Stela and temples, and to look for sub-stelae caches; 3. A map of the environs of Uaxactún, to determine the number, frequency, locality, and possible relations to each other, of house mounds and chultuns, for the purpose of estimating the population; and, 4. Miscellaneous excavations.

Before proceeding with the description of the excavations in Group E [Chapter 28.4], the following additions to the nomenclature used must be noted: 1. The East Mound: the platform mound, 15 feet [38.1 cm] high, upon which stands Temples E-I, E-II, and E-III; this mound bounds the east side of the plaza of Group E; 2. The South Mound: the platform mound, 16 feet [40.6 cm] high, upon which stands Temples E-IV, E-V, and E-VI; this mound bounds the south side of the plaza of Group E; and, 3. Structures A, B, and D: ill-defined constructions encountered below one or more

plaza floors; they are probably low platform mounds upon which stood former buildings which were demolished during the enlarging of the plaza of Group E.

The object of the excavations made in Group E during the past season was to determine the character and relationship of the four floors uncovered during the previous season [Chapter 28.4]. To this end, two main trenches were dug in the plaza, one running east and west across the plaza just north of Stelae 19 and 20, and the other running north and south approximately in the center of the plaza. With the intersection of these two trenches considered as the central point, the trenches extending from this point were called the North, East, South and West Trenches, respectively. All of these trenches, except the West Trench, were started from pits sunk on the edges of the plaza, Pit 3 in the North Trench, Pit 8 in the East Trench, Pit 17 in the South Trench; the trenches then being dug toward the center, 10 feet [3.1 m] wide on the surface and following the topmost floor that had appeared in the pit. When it became evident that this system would not be satisfactory, since the top floor in some cases disappeared entirely or proved to be only a terrace level, the trenches were dug from the center pit toward the edges of the plaza, still clearing only one floor at a time. This procedure was adopted to preclude the possibility of a careless workman mixing sherds from different strata. Narrow ledges of each floor were left extending into one side of the trench, and these ledges proved to be of the greatest assistance in solving the problem presented by the extremely complex system of floors, repair floors and terraces.

The East and West Trenches, whose combined length was only 122 feet [37.2 m], as compared with 256 feet [78 m] for the combined length of the North and South Trenches, were completed first. A cross-section shows six distinct floors in the central area, the bottommost being called Floor 1 and the topmost Floor 6. Eastward from the central pit these floors slope up gradually, approximately 0.21 inches [0.5 cm] per foot. Floor 1 lies at a depth of 42 inches [106.7 cm] below the surface, and Floor 6 at a depth of 11 inches [27.9 cm]. Judging from the quantities of small stones, about the size of English walnuts, that overlie Floor 6, it is probable that there was once another plaster floor above Floor 6, as the Maya, in Uaxactún at least, often laid their plaster floors on a foundation of coarse gravel. Floors 3, 4, 5 and 6 are relatively closely laid, one upon another, but Floor 2, the plaster surface of which is 2 inches [5.1 cm] thick, lies on a gravel bed 6 inches [15.2 cm] deep in the center of the plaza and diminishing toward the west. From this gravel bed great quantities of sherds were recovered.

Toward the western end of the West Trench, almost directly in front of Temple E-VII. sub, a stone retaining-

wall about a foot [31 cm] high was encountered. This wall was found to be contemporaneous with Floor 1, that is, Floor 1 did not continue under the retaining wall but turned up to meet it in such a way that it could be inferred that the retaining wall was built and the floor laid at approximately the same time. Wing trenches to follow this wall were dug, and the structure, which is called Structure A, proved to be a simple platform, the outlines of which can be traced distinctly on the north and east sides. Of the west and south sides only portions remain *in situ*. Probably the missing portions were removed in order to utilize the stones in the building operations incident to the expansion of the plaza or in the erection of Pyramid E-VII sub itself. Floor 2 ends against the retaining wall, but Floor 3 and all floors above it pass over Structure A. In this vicinity, Floor 1, gradually sloping up, apparently, coalesces with Floor 2. Floor 3 is flush with the terrace-like foundation of Temple E-VII sub; viewed from above the terrace and the floor would appear to be one, but in a cross-section view the terrace turns down and Floor 3 joins it. This type of construction was found elsewhere during the season's excavations, and the excavator must constantly be on guard against confusing terraces and floors that join on the same level; obviously, the pavement in these cases is a later construction.

It was discovered that the floor a referred to in the report of last year's work [Chapter 28.4] was actually the above-described temple terrace, and would therefore correspond to Floor 3. Similarly, Floor d corresponds to Floor 6, Floor c to Floor 5, and Floor b to Floor 4.

A re-examination of Stela 20 was made, and it was found that this monument, bearing the date 9.3.0.0.0 (235 AD) must be associated with Floor 6. Stela 19, bearing the date 8.16.0.0.0, 3 Ahau 8 Kankin (97 AD) on the other side of the plaza is also associated with the topmost floor. Obviously, one of these monuments can not be in its original position, if we suppose that the dates cut upon them are synchronous with their erection. Conversely, if both monuments are in their original positions, the date on Stela 19, since it is the earlier, must have referred to some past event at the time when it was erected. It is the writer's belief that one or both of these stelae have been moved, from their original positions.

The East Trench, viewed in cross-section, shows six floors near the central area, but toward the eastern border of the plaza another floor appears between Floors 4 and 3. This is called Floor 3', and the exact point of its beginning could not be discerned. Floor 3, 32 feet [9.8 m] west of the first step on the East Mound, sloped upwards to coalesce with this extra floor and continues as Floor 3' to the East Mound. It would there-

fore appear that the plaza was widened some time after the laying of Floor 3 and previous to the laying of Floor 4. Floor 4 runs under the East Mound, secondary construction. A narrow trench dug into the East Mound revealed a primary construction immediately inside; this was of stucco over a stone core and consists of 13 steps or terraces reaching the top of the East Mound.

A double row of large squared limestone blocks was uncovered, 22.5 feet [6.9 m] west of the East Mound, running north and south across the East Trench. Their function could not be determined, but it is tentatively suggested that they represent blocks taken from a demolished building and re-used as fill for leveling purposes during a period when the plaza was being extended.

Of the South Trench the space available in this report permits only the most cursory description. Seven distinct lines of stones were encountered, two of them double, running east and west across the trench. Wing trenches to determine the extent and function of these lines of stones were ineffectual, except in the case of the two most southerly rows. The southernmost row appears to be a low retaining wall with a batter. It could be followed to a corner on both the east and the west, where in each case the wall turned north. The northeast corner of this structure, Structure D, could also be determined, but within a few yards of the corner, the north wall was permanently lost under the roots of a gigantic Spanish cedar. The northwest corner was found symmetrically placed opposite the northeast corner, but within a few feet of it the north wall again disappeared. There seems to be sufficient evidence, however, together with the evidence produced by the next most southerly row of stones, which resembled the wall of an inner room, to describe Structure D as a platform mound with cut-stone, battered retaining walls, upon which had stood a building.

The South Trench was continued into the South Mound. Little trace of the secondary construction remains *in situ* here, but evidence of primary construction abounds. The northwest and northeast corners of the mound were determined, but further excavation will be necessary to decide whether the small sections uncovered should be classed as primary or secondary. Both corners are rounded, not square, and the blocks composing the walls are massive and well out, leading one to infer they belong to the earlier construction.

By far the most complicated labyrinth of retaining walls, floors, and re-used walls of demolished buildings was uncovered in the North Trench and the extensive excavations that developed from it. Briefly, the salient features may be described as another low platform mound, Structure B, which apparently had either a lower platform projecting from it on the south side, or was partly superimposed on another and ear-

lier platform mound. Further excavation is necessary here. Floor 1 ends against the bottom of the projection on the south side of Structure B. Floor 2 coincides with the top of the same construction. Floors 4, 5 and 6 pass completely over the whole north half of the plaza. Mound E-VIII, secondary construction, extends in terraces into the plaza, some of the terraces coinciding with or terminating against retaining walls of Structure B. No less than five excellently preserved floors pass completely under Mound E-VIII. Upon trenching into this mound, primary construction was encountered almost immediately, leading to the top in nine steep terraces. As these terraces were too high to step up comfortably, a single cut stone had been placed against each riser as a step. Three such stepping-stones were found *in situ*, the mortar in which they had been set still being present. The construction of Mound VIII sub (terraces of well-out stone heavily coated with stucco) is exactly like that of Temple E-VII sub and the primary terracing on the East Mound. A narrow trench was dug through the facing of Mound E-VIII sub into its core, and continued until its face, perpendicular with the front edge of the top of the mound, measured 22 feet [6.7 m] in height. The core of the mound was found to consist entirely of very large uncut pieces of limestone embedded in a hard marl, and the removal of these boulders from the 22 foot [6.7 m] face required so much effort and entailed such risk that the work on the trench was discontinued. There was no evidence that Mound E-VIII sub contained within it any earlier construction; however, as this trench had been dug because a pit on the outer edge of the mound showed five floors passing beneath it, another pit was sunk at the end of the trench and the same five hard floors were encountered, suggesting that any interior structure might conceivably lie beyond the limits of the trench.

Temple E-VII sub, uncovered during the past season, was examined more closely, with special attention to its relation to the various plaza floors. This study proved very puzzling. Floor 2, with which Floor 1 had coalesced just east of Temple E-VII sub, continued under the pyramid on its east side, but a short trench up to the pyramid on its west side indicated that no floors ran under it there. To explain this difference, a painstaking examination of the floors around the north side of the pyramid was undertaken, but the confusion was so great that no satisfactory results could be obtained. Then a narrow trench was dug into the north side of the pyramid, cutting through the north stairway. At this point two floors ran under the temple and two ended against its base. The topmost of these four floors could be identified as Floor 5; the other three could not be connected actually with known plaza floors, though they checked correctly, counting downward, with Floor 4, Floor 3, and the coalesced Floors 2 and 1.

This trench exposed the heavy stone veneer of Temple E-VII sub, and 9 feet [2.7 m] in from the bottom step a crudely laid terraced wall appeared, rising in eight terraces to a point 20 feet [6.1 m] directly under the platform mound on top of the pyramid [Chapter 28.4]. Whether this crudely laid structure is merely a core upon which Pyramid E-VII sub stands, or is an independent structure over which E-VII sub was built, it is not possible to say. at the present time and further investigation will be necessary. Two points should be noted here: the two floors running under Pyramid E-VII sub definitely continued underneath the interior structure; and the fill between this interior structure and the stone veneer of E-VII sub is radically different from the fill encountered within Mound E-VIII, in that it is composed of irregular but distinct strata of soft white marl, gravel and black clay.

Twenty-eight pits were sunk in the plaza of Group E, of which the more important may be briefly described as follows:

Pits 1, 4, 15 and 18 were dug in the northwest, northeast, southwest and southeast quarters of the plaza, respectively, to determine the depth to undisturbed soil. Pit 1 pierced three floors and was dug 5 feet 11 inches [1.8 m] deep; it was left incomplete still penetrating disturbed strata. Pit 4 pierced four floors and was dug 10 feet 4 inches [1.3 m] deep; it was left incomplete, still penetrating sherd-filled ash and charcoal. Pit 15 pierced four floors and struck bedrock limestone at 8 feet [2.4 m]. Pit 18 pierced four floors and was dug 7 feet 2 inches [2.2 m] deep through disturbed strata, finally striking large stones; it was left incomplete at this point. A charcoal and ash deposit was encountered at 5 feet 2 inches [1.6 m] from which artifacts were obtained, including bone awls and needles, crude flint implements, etc.

Pit 9 was dug in the bottom of the East Trench near the center of the plaza, to a depth of 9 feet 9 inches [2.9 m]. At 5 feet 11 inches [1.8 m] stiff fine black clay; was encountered, and below this, at 8 feet 1 inch [2.5 m], a 7 inch [17.8 cm] stratum of small limestone broken gravel full of sherds.

Pit 20 was dug in the center of the North Plaza of Group E. It pierced seven floors and at 7 feet 8 inches [2.3 m] reached undisturbed black clay.

Pits 12, 13, 14 and 28 were dug west of E-VII sub, primarily to determine how far various floors extended westward from the plaza and the depth to bedrock at various points. Floor 5 ended 11 feet 6 inches [3.5 m] west of E-VII sub; Floor 3 ended 16 feet [4.9 m] west of E-VII sub in Pit 12, which was dug 4 feet [1.2 m] to bedrock; Pit 13 reached bed rock at 2 feet 8 inches [81 cm]; Floor 2 ended 39 feet 6 inches [12 m] west of E-VII sub in Pit 14, which was dug 2 feet 6 inches [76 cm] to bedrock. Pit 14 also exposed a badly preserved skel-

eton, lying on solid limestone, head to the north and face down, at a depth of 2 feet 6 inches [76 cm]. There was no funerary furniture and the skeleton could not be recovered.

Pits 3, 8 and 17 were dug as starting points for the North, East and South Trenches, respectively. Pits 7, 10 and 11 were dug during the previous season [Chapter 28.4], Pit 7 just north of Stela 18 (Trench no. 3 in [Chapter 28.4]), Pit 10 east of Pyramid E-VII Sub (Trench no. 1 in [Chapter 28.4]) and Pit 11 north of and under Stela 20 (Trench, no. 2 in [Chapter 28.4]). The nomenclature is here changed because this season's excavations, removing all the upper dirt, completely obliterated the trenches, which were really in the nature of pits.

As a result of the excavations in the plaza of Group E, I believe it is safe to make a few general observations, though the excavations are still incomplete. The complex of structures called Group E appears to have gone through no less than four distinct periods: 1. First occupancy; ash-pits and rubbish heaps formed; 2. Erection of the earliest platforms; Structures A, B, D; 3. Demolition of earliest buildings, expansion of plaza, and erection of the Primary Type structures, Pyramid E-VII sub, etc.; and, 4. Erection of the Secondary Type structures over the Primary Type buildings, Pyramid E-VII.

So far, no mention has been made of the pottery found at Uaxactún and at this writing there is little to be said. Permission has been obtained from the Government of Guatemala to transport all portable objects to Guatemala City, where Messrs. Ricketson and Smith will take up a residence in order to make an intensive study of all sherds. It is possible, however, to make the following general statements, subject to later corrections:

1. No polychrome pottery occurs below the topmost floor of the plaza (Floor 6).
2. Few sherds of any description occur between Floors 6 and 2.
3. The sherds from the deep gravel layer beneath Floor 2 occur in great numbers and are characterized by: a. polished red or black slip; b. horizontal fluting, and some vertical fluting; c. simple silhouette, vases and dishes.
4. Sherds from beneath the bottom floor (Floor 1), in the so-called Black Dirt, are of the following types: a. Human effigy figurines, characterized by extreme simplicity, free-hand modeling, grooved and punched eyes and nipples, rolled fillets around the head, and relative flatness antero-posteriorly. The figurines are all represented as standing rigidly, the legs formed of one piece, down the center of which a groove indicates the line of separation. Not more than a dozen and a half fragments of figurines of this type were found during the season; b. Animal effigy

whistles; of these only fragments were found; c. Sherds of highly polished red or black-wares, incised after firing with parallel lines and in geometric patterns.

5. In Pit 4, in the ash deposit at the bottom, was found a figurine's arm and shoulder of sun-baked clay with a light-brown slip, dull polish.

The above classification attempts no more than the noting of types which appear to be characteristic of their respective strata. Types of pottery occurring more generally are omitted, as are the finer gradations impossible to determine until all the specimens have been thoroughly cleaned and examined.

A. LEDYARD SMITH

Report on the Investigation of Stelae

YB 28:323–325, 1929

An investigation of the stelae at Uaxactún was started on April 1. The purpose of this work was threefold: first, to associate dated monuments with adjoining plaza floors and temples and to determine the reliability of dating the temples by this means; second, to determine the methods used to erect and support the stelae; and third, to discover possible caches under the monuments.

There are 44 stelae in Uaxactún. They are, of course, in different states of preservation, some still standing, others broken off at ground level with bases *in situ*, and some completely uprooted. No study was made of the uprooted stelae, as it proved impossible to find the holes in which they originally stood. Of the 44 monuments, all but seven were examined. Sixteen, were still standing, and 10 were broken off at ground level or slightly above, with their bases still *in situ*; 11 were found uprooted.

This investigation shows that it is not possible to date definitely a temple by the date of the monument in front of it. Generally the floor is broken around the base of the stela, and this condition may be due to the shifting of the stela or to the action of water running down its sides. It may also indicate that the monument has been set through the floor and is therefore of later date than the floor. Even when the connection is perfect and the floor turns up to the monument and is

definitely joined to the temple behind it, one can only say that the temple is probably contemporaneous with the stela. Conclusive evidence that many of the stelae were moved and re-used makes any positive dating of the buildings by means of the stelae unreliable at Uaxactún.

Stela B-5, in B group, will illustrate this point. This stela, of fine hard limestone, was absolutely plain from the floor level up; no traces of carving could be found. Upon close examination, carving was discovered just below the floor level, and one could plainly see that the stone had been chiseled down to remove the carving above the floor level. The carving consisted of a glyph panel, much obliterated, extending to within 8 inches [20 cm] of the base of the stela. Thus the present base of the stela might originally have been the top. Another example is the altar of Stela 9 at Group A; this altar was made from a carved stela (no. 10), and part of the original design may still be seen on the top and bottom. Still another example is to be found at Group E, where an examination of floor conditions seems to indicate that Stela 18 and 19 were set up after Stela 20, which bears a date later than that on 18 and 19.

There were five methods of supporting the monuments. The most common was to place the stela in a hole from 1 to 3 feet [0.3–0.9 m] deep and hold it in position by wedging small stones around the butt and filling with a fine rubble composed of burnt lime, small stones and dirt. A second, frequently used when the stela were set through floors or required additional support, consisted in building a platform around the stela above the top floor. Stela 4, in B group, illustrates this very clearly. A third method was to build the stela into the wall of another structure; thus the base of Stela B-I is held in position by the stones of the lowest terrace of Temple B-V, the butt of the stela extending only 6 inches [15.2 cm] under the floor. A fourth method consisted in building a stone crib below the floor to receive the butt of the monument. There are three examples of this method of support at Uaxactún, namely Stela A6, 6, and A10. These cribs in no way suggest vault construction; they are not nicely fitted, and are made of roughly cut stones. The fifth and most effective method consisted in cutting a hole, 1 to 2 feet [31–62 cm] deep, in very hard marl and shaping it as nearly as possible to the butt of the stela. Between the stela and the marl is tamped a mixture of burnt lime and dirt which acts as a cement.

Caches were found under six of the monuments, and were of three types: 1. eccentric flints, shells, and, worked objects of shell, jade and obsidian; 2. flint and obsidian chips, mixed; 3. obsidian cores and chips, no flint.

The first cache was found under Stela 4, and contained the following objects: eight eccentric flints, three

bats with spread wings shape, three snake shape, two deer-head shape, three eccentric obsidians, deer-head shape, one obsidian core, two small obsidian blades, one jade bead, polished but not drilled, five small jade chips, one small, flat jade figurine, two small, flat shell figurines, two pieces of carved conch shell, two pieces of coral, two small pieces of mineral, probably iron pyrites. These objects were not in a cist, but were found scattered in the rubble under the southwest corner of the monument. The eccentric flints are very similar to those found at Baking Pot (Ricketson 1929); they are probably conventionalized animal forms used with some religious significance.

A cache of similar type was found under Stela A11. It contained the following objects: six eccentric flints, four snake shape, two deer-head shape; two laurel leaf flint blades, two obsidian cores worked to a point at each end; two obsidian cores (possibly eccentric obsidians); four obsidian chips, one sea shell (scallop?), one piece of shell. The flint objects were found around the edges of the monument, and the obsidian and shell beneath its center.

Another type of cache was found under Stela A6. This consisted of 41 obsidian cores, some pointed at each end and others comb-shaped with three teeth; with these was a great quantity of chips and broken obsidian blades. A similar cache was found under Stela A7, containing 30 obsidian cores of the above-noted types and many obsidian chips.

A third kind of cache was found under Stela B2 and A1. Here very little obsidian was found but a great many flint chips, obviously the result of the manufacture of flint implements, were mixed with the dirt under the monuments.

A most unusual find was encountered under Stela 17. Here, under a floor and 6 inches [15.2 cm] from the base of the stela was the mouth of a chultun covered by a flat, circular stone. This chultun had two chambers, one a little to the north and below, the other, directly under the stela. Nothing was found in either chamber.

The results of this investigation of the stelae were disappointing in some measure. It has shown that any certain dating of buildings by means of stelae is impossible, because of the evidence that stelae could be and were moved and reused. Although few caches were discovered, they may be considered important, as the objects found in them conform, in general to the type hitherto found in sub-stela caches and exhibit some new features as well. The methods used to support the stelae show no striking originality or ingenuity, and seem to have been suggested mainly by the type of soil where the stelae was to be placed.

A. LEDYARD SMITH

Report on the Map of Environs of Uaxactún

YB 28:325–327, 1929

On February 25, Mr. Enrique Shufeldt was given the task of mapping the country surrounding the six main groups at Uaxactún. The purpose of this work was to ascertain the number of house mounds and chultuns in the vicinity of the civic center, in order to make an estimate of the ancient population.

The following method was used in, making the map: Two main lines of sight were cut, one east and west, the, other north and south, crossing each other at a point 625 yards [572 m] southwest of the main aguada. The north-south line runs through Groups A and B and the east-west line through, Groups D and E. Additional lines were then cut parallel to the two main lines and 100 yards [91.4 m] apart, and other lines intersecting these at right angles at intervals of 100 yards [91.4 m]. The area thus divided into squares is cruciform, each square being 100 yards [91.4 m] on a side. The arms of this cross, each 400 yards [365.8 m] wide, extend 1,400 yards [1280.2 m] to the north, 1,800 [1645.9 m] to the east, 1,600 [1463 m] to the south and 1,000 [914.4 m] to the west of the point of intersection.

After the squares were cut they were numbered and searched. They were purposely made small, because the density of the jungle made it difficult to see the house mounds, and the search of each square had to be accomplished with a minimum of bush cutting.

The Eastern Arm consists of 72 squares, or 720,000 square yards [0.6 sq km]. Of these squares 24 were not searched, as they lay in Group E which had already been mapped. Twenty-nine squares were bajo, or low swampy land, and 19 were high ground. Nineteen house mounds and three chultuns were found. The house mounds were usually elliptical in shape and were found standing alone, two together in an L shape, or three or four around a court. Sometimes a single house mound was in the shape of an L. The chultuns were not always found in connection with house mounds. All of the house mounds in the eastern arm occur on high ground except in two cases, where large artificial mounds had been built in the bajo and house mounds placed on top of them. In the extreme eastern tip of the mapped area a small aguada or water hole was found.

The western arm consists of 40 squares, or 400,000 square yards [0.3 sq km]. Of these 39 were high ground and one bajo. On the high ground eight house mounds

and four chultuns were found. In this area the chultuns were not connected with house mounds.

In the northern arm there are 48 squares, or 480,000 square yards [0.4 sq km]. Of these 18 are high ground, 14 are bajo, and 16 are in Group A. On the high ground 14 house mounds and four chultuns were found.

In the southern arm there are 56 squares, or 560,000 square yards [0.5 sq km]. Of these 38 are high ground and 18 bajo. On the high ground, 24 house mounds and 17 chultuns were found. Of the chultuns, Chultun 3 is the most interesting. It should really be called a cave, for although a hole of the same type as those used for chultuns is cut through the surface rock, the inside is a natural cave, about 23 feet [7 m] long by 18 feet [5.5 m] broad by 8 feet [2.4 m] high; another and smaller cave can be entered from it through a narrow hole in the southern end and small passages just large enough to crawl into lead off to the north and west. This cave was probably formed by the sinking of the limestone floor, and apparently had been used as a dump, for a great deal of broken pottery was found in it. There is also evidence that it had been used for a long time, because all the types of pottery previously found at Uaxactún were present. Some of the best pottery yet found in Uaxactún came from this cave; in addition to the pottery a beautifully worked laurel leaf flint, pieces of human bone, part of a figurine of the flat type, a carved limestone metate and mano, and a broken limestone comal were found.

In estimating the density of the population per square mile [2.6 sq km], the area of land suitable for dwelling purposes must be considered. Of the 2,160,000 square yards [1.8 sq km] under consideration at Uaxactún, 620,000 square yards [0.5 sq km] were bajo, swampy land unfit for the building of houses, and 400,000 [0.3 sq km] were occupied by complex groups of temples, courts and pyramids obviously not intended to be dwelling places for the common people. Hence, only 1,140,000 square yards [0.9 sq km] of the area considered are suitable for dwellings; this equals 0.37 square mile [0.9 sq km], in which were found 63 house mounds. If we consider the average number of persons in a Maya family living in one house to be 7, this would give us 1,187 persons per square mile [2.6 sq km] of habitable land, exclusive of bajo.

28.10.

A. LEDYARD SMITH

Archaeological Work at Uaxactún

YB 30:110–112, 1931

The ruined city of Uaxactún, in the Department of the Petén, Guatemala, was discovered by Dr. Morley in 1916. Study of the hieroglyphic inscriptions upon its monuments indicated that it had been both the oldest longest occupied of all known cities of the Maya Old Empire. Hence, in spite of the great difficulty of carrying on excavations at a site buried in dense tropical jungle and to be reached only by long river and mule-train journeys, Dr. Morley recommended its investigation by Carnegie Institution. It gave, in his opinion, exceptional opportunity for studying the earlier phases of Maya development and for following the progress of culture through the period of greatest brilliance. The project was inaugurated in 1925 under direction of Mr. Ricketson and has continued present time. In 1931 the writer was in charge, assisted by Mr. Smith, Mr. Monroe Amsden acting as business and transport manager.

During previous years attention had been devoted to Group E, a collection of temples surrounding an open court or plaza. Former *Year Books* record the discovery and clearing of the excellently preserved Structure E-VII and the finding under the plaza floor of stratified refuse deposits laid down at a time when Maya civilization was apparently just taking shape. In 1931 we resumed work in the plaza of Group E; carried forward the investigation of Group A, begun last year; tested house mounds; sunk a pit into a natural well-like cavity in the rock; and made casts of a number of monuments.

At the opening of the season decision had not yet been reached as to whether or not the excavation of Uaxactún should be continued beyond 1931. We therefore planned to bring to completion all units of work which had been begun in former years. At the same time, but without committing ourselves to new activities of major scope, we wished to conduct certain tentative investigations in order to make recommendations for the future. To Group E first attention was accordingly directed and a month was devoted to sinking to bed-rock and continuing all the way across the plaza's 10 foot [3.1 m], westward-running trench that had been started at its north end. The purpose of the trench was to cross-section the plaza and determine if it had been built up. It was found that, to level the court, retaining walls had been built at the east end. This had not been necessary at the west, as the limestone dips eastward, being only about 2 feet [61 cm] below ground-level at

the west. The deposit proved to be of great interest, containing stratified *débris* and fill which yielded large amounts of broken pottery, representing sequent periods of the city's early history. Burials were also encountered. In the underlying limestone we encountered a series of rock-cut chambers similar to, but more carefully made than, the *chultunes* or reservoirs found in many parts of the Maya area. Pyramid E-IX was outlined by removal of fallen material encumbering its sides and base. It proved to have stairways on all four sides. The temple which once crowned the structure had completely disintegrated, but there came to light a ceremonial cache of two pottery dishes, set rim-to-rim, containing seven flint implements surrounded by two large obsidians, two flint daggers and a large flint chipped to eccentric shape. The annex-mound on the south side of Pyramid E-VII, trenched during a former season, was further investigated and found to contain a small plastered pyramid, E-XII, which once had staircases on four sides. Some of the original red paint still adhered to a coating of plaster. In excavating the mound we uncovered the south side of the secondary structure which had been built over Primary Pyramid E-VI and which had preserved the latter in the splendid condition in which it was found in 1928. The secondary structure, having been exposed to the weather and the destructive encroachment of the jungle, had been almost entirely ruined, but at this point a portion of it had been protected by the annex-mound. It proved to have masks superimposed upon those of the earlier pyramid. Mounds E-X and E-VIII were also excavated and found to be a single structure. We trenched through E-XII and determined that it was a long, low platform with no building upon it.

Work in Group A, a complex of mounds, buildings and courts with many stelae, located on a ridge about a half mile [0.8 km] from Group E, was started a month after the expedition arrived at Uaxactún. Attention was devoted to Pyramid A-1, which had been partially excavated in 1930. Like so many Maya constructions, it proved to have grown to its final form by several accretions. In this case four pyramids, each of a different type of architecture, had been built one upon the other. The latest pyramid was in very bad condition; the next to latest, or tertiary, revealed a small culminating sanctuary containing some very fine polychrome pottery. Below the sanctuary lay the top of the secondary pyramid. Here was made the most important find of the year: two vaults with burials accompanied by magnificent series of 10 polychrome mortuary vessels in perfect condition. On of the pieces, a cylindrical vase decorated with a procession of priests or deities in full regalia, bore an Initial Series in the monumental manner apparently recording the date 7.5.0.0.0, 8 Ahau 13 Kankin (?). Comment upon this inscription,

which does not lead to the terminal date actually recorded, and which indicates a date not only much earlier than any hitherto discovered, but one which does not accord with the sophisticated style of painting, must be withheld pending its study by Dr. Morley and other hieroglyphic specialists. A peculiar circumstance was the finding in the vessel of the skeletons of 104 shrews, a number equaling eight times 13, the two figures involved in the day and month counts expressed in the Initial Series.

The complex architectural conditions encountered and the great care necessary in noting and removing the contents of the burial chambers resulted in Pyramid A-I not being completely excavated. The primary or innermost structure has not yet been touched.

Among the exploratory investigations mentioned above was the testing of A-V, a large many-roomed building of the so-called "palace" type. The three rooms cleared were found in reasonably good condition. The architecture of Old Empire "palaces" not being well understood, and their function, both in the Petén and in northern Yucatán, being still a matter of doubt, it is felt that further work in this Uaxactún example would amply repay the time and expense involved. Another test-project was the trenching of two house mounds, a quarter-mile [0.4 km] from Group A. An attempt was made in 1929 to estimate the size of the population of Uaxactún by means of a count of the house mounds in a given area, but no excavation having been done in them, it was not certain whether or not they had been occupied contemporaneously, nor, indeed, whether they had actually been the substructures of dwellings. Our trenches demonstrated that these low platforms had, in fact, supported houses of perishable materials. Upon their floors were burials. Pottery was collected which may throw light on the question of their relative date.

A pit was sunk into a "sink hole" or natural well. At a depth of 20 feet [6.1 m], bottom had not yet been reached although potsherds and pieces of obsidian were still being encountered in the black clay with which the well is filled. The shaft should certainly be continued, as it offers possibility of yielding important stratigraphic information.

An arduous but necessary undertaking, was the making of paper squeezes of seven of the dated stone monuments. Upon these are carved some of the most important of all Maya inscriptions. It was therefore felt that a permanent record should be made in the form of casts which could be preserved and studied in museums. Uaxactún is not only a very difficult spot to reach, but the monuments might well be lost to view for centuries should the site be allowed to revert to the impenetrable jungle which the expedition has temporarily cleared away.

The party was most fortunate in having with it three biologists from the University of Michigan: Dr. A. Murie, mammalogist; Dr. J. Van Tyne, ornithologist; and Dr. H. Bartlett, botanist. In addition to being most valued field companions, these gentlemen were able to supply us with many interesting and significant data upon the flora and fauna of the Petén and so enable us to begin to reach an understanding of the environment in which the ancient Maya lived. Dr. W. Cooke of the United States Geological Survey also worked at Uaxactún. He studied the geology of the region, paying particular attention to the bajos or log-wood swamps. Dr. Cooke believes that these low-lying areas, which are now overgrown with a low and almost impenetrable scrubby bush, may formerly have lakes. If further examination confirms this hypothesis, and if the bajos can be shown to have contained permanent water during the period of occupancy of this region by man, many hitherto puzzling problems of water supply and of transportation will be solved.

As result of the season's work, the writer strongly recommends continuation of the Uaxactún project. He feels that Pyramid A-I should be completed; that the palace, A-V, should be cleared and studied; and that attempt should be made to make as full as possible the already very significant, but so far not continuous, ceramic record. Much work, furthermore, still remains to be done in biology, meteorology, soil conditions and other non-archaeological lines.

28.11.

ALFRED V. KIDDER

Uaxactún

YB 31:97–100, 1932

The Section's second major archaeological project in the Maya field is the excavation of Uaxactún, the Old Empire city in northern Petén, Guatemala, which was discovered by Dr. Morley in 1916, and at which, under the successive leadership of Frans Blom, O. G. Ricketson, Jr., Monroe Amsden, and A. Ledyard Smith, work has been carried on since 1924. Uaxactún was selected by Dr. Morley, for intensive work because it was, on the evidence of its hieroglyphic dates, both the oldest and the longest inhabited center of Maya culture. The digging of past years resulted in uncovering a very beautiful early structure embalmed, so to speak, within a

later pyramid; and in the discovery of stratified deposits of still earlier times which carry the story of Maya development back to a period doubtless far antedating the first stone-carved records. For accounts of the excavations at Uaxactún, see [Chapters 28.2–28.10]. These very valuable finds, architectural and stratigraphic, were made in a quarter of the city known as E-Group. They amply justified Dr. Morley's selection of Uaxactún for investigation, in spite of its inaccessible situation and the consequent high cost of conducting excavations there.

In 1931, concurrently with the winding up of work in E-Group, Mr. Robert E. Smith commenced the study of A-Group, the largest and apparently the most important complex of buildings at Uaxactún. A spectacular find of mortuary pottery rewarded this effort [Chapter 28.10; A. Smith 1934]. During the past season the principal effort of Mr. A. Ledyard Smith and his staff, Robert E. Smith and Robert Wauchope, was devoted to further exploration of A Group.

It will be recalled that the Monjas, or "Nunnery," at Chichén was so-called because of its great number of small, cell-like chambers. Buildings of this sort, sometimes referred to as "Palaces," are found in many parts of the Maya area. Their function is not as yet really understood, although, as the above names imply, they have been thought perhaps to have served as residences. The palaces of the Old Empire are very little known. Hence, in spite of the magnitude of the task, a large palace in the A-Group, Structure A-V, was attacked this year by Mr. Ledyard Smith, reconnaissance digging in 1931 having indicated that under masses of fallen material the lower walls of many rooms remained in a good state of preservation.

The building, which rests on a low, roughly rectangular platform of masonry, is some 150 feet [45.7 m] long by 130 feet [39.6 m] wide. Its greatest height, as it now stands, is nearly 50 feet [15.2 m]. The structure consists of four courts surrounded by blocks of cell-like chambers, whose vaulted roofs have, for the most part, collapsed. Of the 4, the North Court and the Main Court, with the rooms adjoining them, were cleared during the season. The excavations showed that the courts lay on different levels, access from one to another having been gained by stairways. The rooms composing the blocks or galleries vary greatly in length; in width they run from 4 to 6 feet [1.2–1.8 m]. Five constructions, tentatively identified as shrines, were found in the construction dividing the Main Court from the South Court. Each one consists of an ante-room and an inner chamber or sanctuary. In the sanctuary of Shrine I there was found a stela bearing the date 9:3.0.0.0.

Under the stela was a cache of eccentrically chipped flints.

Throughout the palace Mr. Smith constantly noted evidenced of changes in the building, old construction having been buried below later additions. There is an abundance of sealed doorways, and many rooms and even whole wings have been added. The palace was evidently at first a small structure, which grew by a slow process of accretion. Various peculiarities of architecture have, been noted as characteristic of different periods. Three distinct types of rooms, for example, are already recognizable; and with complete excavation, which it is hoped may be accomplished in 1933, a true architectural stratigraphy should become evident.

Mr. Smith believes the palace to have been a dwelling place, because the walls of many rooms show evidence of cooking-fires, usually in sheltered corners; and because of the presence of debris of occupation in the form of animal bones, fragments of pottery and broken implements. The shrines, however, indicate that ceremonial practices were carried out in the building; and it is indeed possible that it was originally erected for purely religious purposes, the traces of a baser use dating from late times. Study of the pottery from the different levels and of the distribution of the areas smoked by cooking-fires maybe expected to solve this problem.

While the excavation of the palace was going on, Mr. Robert Smith devoted himself to the examination of certain small pyramidal structures, which, on the evidence of Pyramid A-I, excavated in 1931, might, it was thought, contain burial vaults! This work was planned with the double purpose of studying mortuary customs and of recovering, if possible, additional specimens of the finer sorts of pottery which, as a rule, can only be found in graves. The results were highly gratifying.

Pyramid B-VIII was first opened. From its summit platform a vertical shaft, the mouth closed by a red-painted stone slab, descended to a rectangular chamber 16 feet [4.9 m] below. In the rough masonry of the chamber and of the shaft were footholds and offsets. On the floor lay the skeletons of two adult females, a child and an infant fetal bones were, intermingled with those of one of the adults. Seven pottery vessels, four plain, three with polychrome decoration, and some shell beads, constituted the mortuary offerings. Pyramid B-XI, in addition to several caches of pottery and obsidian blades, yielded a coffin-shaped burial vault 7 feet [2.1 m] long, 2 feet [61 cm] wide and 18 inches [45.7 cm] deep. One end was floored, walled and capped with massive stones; the other end, of much cruder construction, appeared to have been added at a later time. In the vault were the skeletons of two females, accompanied by pottery, a necklace of nearly 500 shell and seven large jade beads, and another necklace of 32 beads of iron pyrites.

Against the base of Pyramid C-I, but evidently constructed before the erection of the pyramid, was a small room-like chamber 6 feet [1.8 m] long, 4 feet [1.2 m] wide and 5 feet [1.5 m] high. On a low, centrally placed dais or altar were the bones of an adult male whose body had originally been placed in a sitting posture with legs crossed, Turkish fashion. Offerings were: four pottery vessels, one a black bowl with red and green decorations; an alligator head pendant of jade, and the fragments of what had evidently been a mosaic mask.

Mr. Smith believes the vault in Pyramid B-VIII to have been a family burial chamber, the indications of such use being the several skeletons of various ages and the arrangement (removable lid, steps, etc.) for ready access to the tomb. The crypt in C-1, on the other hand, he tentatively identifies as a shrine in which the body of a notable, wearing a ceremonial mask and possibly prepared to resist decay, may have been placed, for worship.

Less spectacular, but of doubtless even greater ultimate importance, was Mr. Robert Smith's discovery of a well-stratified rubbish deposit in the A-Group. Partial excavation of this midden yielded great numbers of potsherds, including a large percentage of pieces of the finer decorated wares. The material, being all of later date than that taken in former years from below the plaza of E-Group, will serve, when studied, greatly to lengthen the known ceramic sequence at Uaxactún; it will provide a key to the relative ages of the otherwise undatable isolated finds in caches and tombs; and it is hoped that it will link the Uaxactún series to that of Holmul, the only other city of the Petén whose pottery is now, known. Mr. Wauchope spent a considerable part of the season in a very careful examination of certain small elevations thought to be house mounds. Of such mounds there are literally hundreds in the vicinity of Uaxactún. As they have been used as basis for estimates of population, it was thought desirable to continue the work begun on them in 1931, in order still further to check their identification as places of residence and to seek evidence regarding the domiciliary structures which may have been built upon them. Mr. Wauchope completely excavated four mounds; a fifth was less thoroughly investigated. Three proved to be typical house mounds, long narrow, artificially filled platforms with dressed limestone retaining walls; one or more terraces; and either plastered or unplastered floors, apparently once covered by perishable superstructures. The fourth was presumably religious in function. It consisted of a platform with a sequence of several plastered floors, upon the uppermost of which were low stone walls dividing the space into four very small rooms, probably once covered by a perishable roof. The fifth structure was the central element of a group of which the fourth and one of the above-

mentioned house mounds formed the other units. The building had had masonry rooms with vaulted roofs. It is uncertain whether this was a residence more pretentious than usual or whether it was a small temple, a shrine perhaps, for a group of dwellings. In the mounds, Mr. Wauchope found 11 burials, many stone artifacts, numerous potsherds and 14 vessels.

28.12.

A. LEDYARD SMITH AND
ROBERT E. SMITH

Excavations at Uaxactún

YB 32:92–95, 1933

The eighth season's work at Uaxactún, the Old Empire city in northern Petén, Guatemala, was carried on under the direction of Mr. A. Ledyard Smith with the assistance of Mr. Robert E. Smith and Mr. Francis Richardson. A. L. Smith and Richardson arrived in camp on March 5. Robert Smith remained in Guatemala City, studying the pottery recovered in 1932, until March 31, when he joined the expedition. The party was at Uaxactún until June 6, at which time they left for Guatemala City to study and write up the material acquired during the season.

During the first weeks in the field, activities were limited to the excavation, in A Group, of Structure A-V, a fine example of the so-called "palace," or complex multi-chambered building, a type which, in the Old Empire, has hitherto been very little investigated. The investigation of A-V was started at the end of 1931 and continued in 1932. At the end of the latter season a good deal of light had been thrown on the question of the purpose of this sort of structure. It had also become evident that it would yield a true architectural stratigraphy, which could be correlated with ceramic finds. The program for 1933 was therefore to complete the excavation of the outer structure of A-V as far as possible, and to begin work on the earlier buildings buried underneath, in order to collect samples of pottery from below floors of various periods and so obtain a ceramic as well as an architectural stratification. Pottery recovered was then to be compared to that of E Group (upon which the ceramic periods of Uaxactún had already been established); it was also to be checked against the pottery obtained from a well-

stratified rubbish heap, prolific in sherds, which was discovered in 1932 near the edge of the plaza south of the Palace.

On his arrival, Robert Smith started work on the rubbish heap mentioned above. He enlarged his 1932 pit and isolated a column of refuse for stratigraphic study. In addition to this he partially excavated Temple A-XV, to secure further information on pyramids and their superstructures, and sank exploratory pits in and about B Group in search of more middens.

Richardson cleared two adjoining *chultun*, or jar-shaped chambers cut into the limestone bedrock, at the base of A-XV, each of which yielded a skeleton in very poor state of preservation. He also made a plane table map of A Group showing all elevations, the detail of excavated structures, the probable position of unexcavated walls, and the extent of the mounds covering unexcavated buildings.

A-V, the Palace in A Group, rests on a low, roughly rectangular platform of masonry some 280 feet [85.3 m] long and 240 feet [73.2 m] wide. Its greatest height, as it stands today, is nearly 50 feet [15.2 m]. This building consists in the main of four courts, all but one of which are surrounded by rooms, whose vaulted roofs have in most instances fallen in. The exception is the East Court, which has rooms on but three sides, the east or remaining side consisting of a long, low platform from whose top an unusually broad stairway leads down into the East Plaza. The courts lie at different levels, access from one to another being gained by stairways. The Main Court and the South Court with their adjoining rooms were cleared in 1932. Pits were dug through their floors revealing earlier constructions which had been buried in the process of enlarging the Palace.

During the 1933 field season, excavation of the outer structure of A-V was almost completed. All the upper rooms, the East Court and the rooms overlooking it have been uncovered, as well as a portion of the North Court. So far, 55 rooms of the outer structure have been cleared. These rooms vary greatly in length, width, height and function. Three distinct types of room construction have been found in stratigraphical position. Differences in walls and vaults control, to a great extent, the width of the rooms, the earliest being much narrower than the latest. Early walls and vaults are built of flat uncut stones laid horizontally and held together by the abundant use of cement, the whole roughly plastered. Late construction is of well-cut stones veneer vertically against a hearting; the vaults consist of nicely fitted beveled stones approaching in shape the specialized vault stones of northern Yucatán; all masonry is smoothly plastered. Continued excavation beneath the floors brought to light a buried pyramid under the Main Court and, under the South Court,

a series of buried rooms which in turn had been built over a terrace and against an earlier room opening thereupon. Several hitherto unexplored parts of the outer structure have been penetrated, and earlier construction exposed. At the present stage of the investigation, it appears that the Palace must originally have constituted a small group of independent buildings, which were joined together and added to until they became a single great unit.

The excavations yielded a great number of artifacts, sherds, and figurines which throw much light upon the function of the Palace, and upon the appearance and dress of its inhabitants. Most of the material so far found comes from above the floors of the courts and rooms, but whenever these floors have been penetrated different types and shapes have occurred. Animal and human bones were found in abundance above the floors, usually in sheltered corners. The human bones, as well as those of animals, show signs of cutting. Many of the human long bones had their extremities removed, and the parts of the shaft still connected to the extremities are cut longitudinally. Such specimens were confined to the latest deposits; hence if they indicate cannibalism, it seems only to have been practiced after the general break-up of the Old Empire.

Two new stelae were discovered in the Palace, one carved and one plain. The latter was standing in position, but had been covered by later construction, the former lay in the rubble under the floor of one of the latest rooms. This stela, which is only a fragment, bears the date 9.5.0.0.0. Seven burials were found, some under the floors of the courts, some in the masonry of benches in rooms, others above floor-level with no protection except a few rough stones placed around them. Both sexes and all ages were represented. In every instance the skeleton was flexed. There were very few mortuary offerings. Most of the bones were in a good state of preservation.

One of the most interesting finds in A-V was a fresco which once covered the whole back wall of a room. It shows traces of red and orange, but for the most part is in black lines. Unfortunately, more than half of it had been destroyed by roots and the fall of stones, but from what remains it is clear that a scene of action was depicted. Figures in full costume carrying spears and standards and others dressed only in loin cloths face each other from either end. In the lower right-hand corner is a double-headed serpent with fish swimming into its gaping mouths; and in the corresponding position at the opposite end is a temple in outline. The latter is of exceptional interest, for it shows a complete roof comb. This is our only evidence as to the nature of this crowning feature of, the Uaxactún temples.

To sum up: The work on the Palace during 1933 resulted in recovery of a definite architectural stratifi-

cation, which shows a gradual and logical development of wall and vault construction. The pottery so far taken from below floors of various periods correlates with the building sequence; it also fits perfectly into the pottery sequence previously established, and with that of the pottery from the stratified rubbish heap near A-XV. The sherds from below the earliest rooms belong to Ceramic Period II. From this and other evidence the existence of the Palace must have been an extremely long one. Mr. A. L. Smith believes that this building had a dual function, residential and religious, and that the latter was secondary to the former. Shrines with their altars and stelae indicate ceremonialism, but all other rooms show signs of having been lived in. The walls of many are blackened by cooking-fires and on their floors is debris of occupation in the form of animal bones, fragments of pottery, and broken implements. These remains can not all be attributed to people clinging to the site after its general abandonment, or to later wandering tribes, because similar evidences occur in some of the earliest buried rooms. That there was a post-Old Empire occupation is, however, certain. Rooms whose vaults and outer walls had fallen were, in some instances, roughly blocked off, rather than properly repaired; refuse sometimes lies upon debris of disintegration; burials were made above floors; there is suspicion of cannibalism. All this is characteristic of a degenerate people, but who they were is still a problem.

R. E. Smith conducted excavations in Pyramid B-VIII to determine whether or not the burial chamber discovered by him in 1932 [Chapter 28.11] was constructed before or after the erection of the pyramid. It was found that the burial chamber was erected on the platform of a low pyramid hewn from the solid limestone bedrock. The mortuary chamber formed the core of the additional terraces built up from this natural mound.

Pyramid Temple A-XV was also investigated. Architecturally it corresponded to the earliest member of the Pyramid A-I complex. Its superstructure had been a one-room masonry temple, with a single doorway to the south. The walls of the temple were made of small, roughly cut stones set in thickly spalled mortar and heavily coated with plaster (an early architectural feature at Uaxactún). Directly south of the doorway and resting on the frontal platform was a hollow altar(?) filled with shrew bones. Burned potsherds covered the floor of the temple room, the altar and the frontal platform adjacent to the doorway. About 3 feet [91 cm] below the temple floor two small adjoining crypts were uncovered. One yielded a cache of obsidians and eccentrically shaped flints; the other a poorly preserved baby burial. The plastered walls of both crypts were draped with what appeared to be charred rope, of

which several fragmentary specimens were saved. A second cache of eccentrically shaped flints and obsidians, together with a deer antler, lay above the crypts.

An undated Stela (A-15), broken in two places, was discovered facing the center of the south stairway. Its butt penetrated about 15 inches [38 cm] below the floor at the pyramid base and was associated with a cache containing four eccentric flints, one eccentric obsidian, one conch shell, four jade beads, and five lancet-like obsidian blades. In line with Stela A-15, but about 7 feet [2.1 m] farther south, was a large, round unsculptured altar supported by three stones.

In addition to work on the above pyramids, R. E. Smith carried out extremely important investigations in refuse deposits. Success in study of ceramics at any given site is dependent upon finding an abundance of stratified material. At Uaxactún, an analysis of the sherds found between plaza floors in E Group, within multiple pyramidal construction in Pyramid A-I complex, and associated with various house mounds, had led to a preliminary chronological classification. Not until 1932, however, was a well-stratified and prolific rubbish heap discovered just off the plaza south of Palace A-V. A trench was dug through this midden from south to north and in 1933 a column 10 feet [3.1 m] square was excavated layer by layer. Although the 30,000 potsherds removed from the column have not yet been thoroughly examined, R. E. Smith's study has already showed that polychrome wares existed in each of the six strata; that certain vessel shapes disappeared and new ones took their place; and that three or possibly four sequent periods of pottery making were represented. Finely decorated wares and especially painted pieces were plentiful and excellently preserved. This very valuable material renders it for the first time possible to work out in detail the gradual development of decorative design at Uaxactún. Beside pottery, Pit 14 column yielded bones, both human and animal, implements of bone, flint and obsidian; and beads of shell and jade.

The existence of the stratified midden in A Group suggested that careful searching elsewhere might locate other deposits which would serve to correlate ceramically the other temple groups of the city. As, experience has shown that such deposits may often be found in low-lying areas near buildings, five pits were sunk in the environs of B Group, but without success. It would seem logical to believe that each group had its own dump. Absence of middens, as in B Group, might, in R. E. Smith's opinion, be due to periodical removal of debris for use as filling material in building operations. He also points out that if this practice was general, it might be dangerous to establish chronological sequences on the basis of pottery taken from the interior of substructures.

28.13.

A. LEDYARD SMITH

Uaxactún

YB 33:82–86, 1934

The ninth season at Uaxactún opened on March 2 and closed on May 2. The work was in charge of A. Ledyard Smith, Edwin Shook serving as assistant and cartographer. Robert E. Smith spent the winter at the Institution's laboratory in Guatemala City, studying the pottery collected from this site during the last two years.

The excavations which have been in progress at Uaxactún since 1926 were undertaken to throw light upon certain definite aspects of Maya history. Uaxactún, according to the evidence of the hieroglyphic dates, was the oldest of Maya cities; and, by the same criterion, it was the longest inhabited of all the Old Empire centers. Because of its antiquity, it was thought that it might contain materials illustrating the very little-known formative period of Maya culture; because of its size and its central location it was certain that it would yield valuable information as to Maya civilization in its prime; and because of its occupancy until the end of the Old Empire period, there was hope that it might provide evidence as to the causes for the abandonment of the Old Empire cities and perhaps serve to bridge the archaeological gap which now exists between the Old and New Empires.

Important data upon the formative period were recovered by Dr. Ricketson and Mr. Smith in 1928–31 inclusive at Group E, one of the principal temple clusters of the city.

As has been stated, Uaxactún was believed to be a favorable site for study of Maya culture during the Old Empire. This expectation has been realized by the results of excavation of sundry minor buildings, tombs and middens reported upon in previous *Year Books*; but particularly by three seasons of intensive digging in Unit A-5, the so-called "palace."

Very broadly speaking, the major structures of the Maya may be divided to two groups. One consists of fairly small buildings with simple ground plan usually set on relatively high substructures. As a rule, each contains inner chamber which seems obviously to have been a shrine. Such buildings are probably to be identified as temples. The second group is made up of very much larger edifices, erected on lower substructures. Their ground-plans are more complex. They possess many rooms, arranged, for the most part, in tiers. They have been thought to have been domiciliary, the abodes presumably of priests or rulers, an idea reflected by such names "Nunnery" and "Palace." The true pur-

pose of the so-called "palaces" has not, however, surely been determined, nor, prior to the excavation of Structure A-5 at Uaxactún, had an Old Empire example of this type been more than cursorily examined. Work upon A-5 in 1932 and 1933 proved it to consist of many vaulted rooms grouped about enclosed courts [Chapters 28.11 and 28.12]. Smoked walls and the presence of debris of occupation served to uphold the residential theory; while shrines indicated that it was not entirely devoted to secular uses. Careful study of the abutting of walls and the superposition of building increments showed that A-5 had grown by accretion over a considerable period, during which there took place definitely recognizable changes in architectural practice [Chapter 28.12].

The program for 1934 contemplated completion of the excavation by clearing the still undug north side and by disencumbering early construction already partially exposed under the South and Main Courts. Mr. Smith also wished to collect further ceramic material and hoped to discover additional burials.

By the close of the season the entire outer or late buildings had been finished. Nine new rooms were cleared on the north side of the North Court, bringing the total count to nine shrines and 61 rooms. The walls of the North Court rooms are of late (Type IV) construction. The rooms themselves would seem to have been roofed with wood and thatch, as insufficient ancient building material was found inside them to justify belief, in the former presence of stone vaults.

The excavations under the South and Main Courts proved to be of the greatest interest. At the end of the 1933 season six buried rooms had been uncovered under the South Court. Five of these were of Type II construction and one of Type I. During the past season four more buried rooms of Type I were excavated, one under the South Court and three under the Main Court. In addition to these, two shrines, two low pyramidal substructures, a platform, six stairways, a buried court, a dated stela and three burial vaults were uncovered. It appears that the nucleus of the Palace was a raised court with pyramidal substructures on its east and west sides, which supported rooms looking out over the court. This was later covered by the present Main Court.

Between the building of the nuclear structure and the addition of the last increment to the main structure there were five main periods of construction. There were thus seven periods, four of Type I construction and one each of Types II, III and IV. There is evidence of several periods of enlargement during Period IV. Additions were made upward as well as outward. Old rooms were filled in and others built in front of them to increase the area of the substructure. In some cases the upper parts of rooms were torn away, to make room for

later courts. The earlier construction was only removed when it would have been in the way of later buildings. This would seem to indicate that abundance of easily worked stone was at hand, because the well-cut stones of the buried rooms were not reused. It is to be noted that some of the earliest rooms were in continual use throughout the whole life of the Palace, and that they are often in the best state of preservation.

A great many sherds were recovered from under floors of the various periods. Although this material has not as yet been studied, it seems probable that it will fall readily into position in the ceramic sequence already established for Uaxactún. Previous to 1934, practically no whole pottery vessels had been found in the Palace, but during the past season over 80 such specimens were recovered from burial vaults below some of the earliest construction. Among the pieces recovered were some new types, the most outstanding being richly incised vessels in the shape of seated animals and men. These vessels, which were used to contain offerings, are divided at the waist, the lower part serving as the container, the upper part as the lid. Under Shrine II a cache of nine eccentric flints was uncovered. This is the second cache of nine such flints found in the Palace. The other came from under the carved stela in Shrine I.

Up to the close of the 1933 season, nine burials had been discovered in the Palace, some under floors of courts, some in the benches of rooms, and others, above floor level with no covering save a few rough stones. In every instance the skeleton was flexed and practically no mortuary offerings were in the graves. No burials in vaults had been found. In 1934 eight more burials came to light. Three were of infants. The remaining five were adult skeletons buried in vaults. Two of the vaults were long, low tombs, just large enough to hold a body extended at full length. The sides were made of rough stone capped with large flat slabs. Two others were carved out of the solid limestone below the earliest rooms of the Palace. One of these two was 12 feet [3.7 m] long, 8 feet [2.4 m] wide and 3.5 feet [1.1 m] high. The opening at the top was closed with seven large capstones. The entrance was through the floor of an early room. The last burial found was put through the floor of the buried court under the Main Court. This vault was made in the style of one of the early rooms and was well plastered. At the west end there was a stairway leading down into it from the level of the Buried Court. This end was locked up after the burial ceremony. Especially interesting was the construction put up in conjunction with this burial. On the level of the Buried Court, two enclosures with low, thin walls were built, one to the east and one to the west of the vault, with doorways leading out toward the burial. To the south was a long,

low, thin wall running east and west with a door-way in the center. This wall joined walls projecting from the rooms mentioned above, so that the burial Vault was completely surrounded. Inside the walls the floor of the Buried Court had been punctured with rows of post holes, from the position of which it was obvious that a canopy of some sort had been stretched over the whole area. It seems probable that a great ceremony took place at the time of interment, after which the whole Buried Court was filled in and raised to within 6 inches [15.2 cm] of the level of the present Main Court. There are several instances in the Palace where immediately after a burial in a large vault had been made, the room or court through the floor of which it was sunk was blocked off or filled in and another construction built on top of it. This would lead to belief that after death and burial of a great ruler his successor added to the Palace and changed it to his own liking.

A new stela, dated 9.0.10.0,0, was discovered underneath the floor of Shrine II. It was standing *in situ* and was connected with Type I construction. In 1933 a fragment of a monument bearing the date 9.5.0.0.0 was found in the fill under the floor of one of the latest rooms. This indicates that the minimum amount of time between the use of the Buried Court (Type I construction) and the period of Type IV was 88 years, although it was doubtless very much longer. The total life of the Palace must, indeed, have exceeded 500 years, as it was built subsequent to 9.0.10.0.0, and it was apparently continuously occupied until the abandonment of Uaxactún, which took place after 10.3.0.0.0.

During 1934 Structure A-XVIII was excavated and mapped. It is a two-story building of Type I construction, which Mr. Smith believes to have been used as a dwelling. The upper story has mostly fallen, but the lower rooms are practically all intact. Further investigation was carried on in the Type I Structure B-XIII and Mr. Shook remapped A-Group and the causeway connecting it with B-Group. This map shows the walls of all excavated structures *in situ*, the gross area covered by unexplored mounds, fall and tentative reconstructions of the ground-plans of unexcavated buildings.

The investigations outlined above, with those of former years, have yielded much valuable information as to the architecture and burial customs of the Old Empire. And when study of the large collections of potsherds and complete vessels has been completed, we shall have an excellent understanding of the ceramic history of Uaxactún. Classification and description of the wares and determination of their chronological sequence should also allow us to correlate the pottery periods of Uaxactún with those determined by Vaillant for the nearby city of Holmul. On the basis of the two series, it should be possible to place ceramically any other Old Empire sites in the Petén from which

specimens can be obtained. This will be an important advance, as many cities contain no hieroglyphic dates. Furthermore, detailed knowledge of the Uaxactún types will enable us to identify trade-pieces and to recognize style-borrowings, so that we can eventually obtain chronological cross-linkages with other centers in the Maya area and even beyond its borders. And, specifically, it may well be possible, by means of the pottery, to work out both time relations and cultural contacts between the New and Old Empires.

Already the work at Uaxactún has brilliantly justified the long and firmly held belief of Dr. Morley that this city would yield outstandingly significant data for the reconstruction of Maya history. And the materials gathered there by Dr. Ricketson and Mr. Smith have not as yet yielded a tithe of information inherent in them. Only when they are fully digested and made available through publication, and when comparative studies are undertaken, will their great value become fully apparent.

28.14.

A. LEDYARD SMITH

Uaxactún

YB 34:115–118, 1935

The tenth season at Uaxactún opened on February 23 and closed on March 18. The work was in charge of A. Ledyard Smith; Robert E. Smith and Francis B. Richardson served as assistants, and Edwin Shook as surveyor.

The greater part of the season was devoted to continuation of the excavation of Structure A-V, the so-called "Palace." This great multi-chambered building was originally chosen for investigation because no Old Empire example of its type had previously been excavated. Work on A-V began at the end of the 1931 field season and continued through the winter of 1932, 1933 and 1934. For statements regarding the archaeological significance of Uaxactún see [Chapters 1.4, 1.10, 28.2 to 28.13]; for accounts of earlier work on Structure A-V see [Chapters 28.11 and 28.12].

At the close of the past season the whole outer structure of A-V had been uncovered, and earlier walls and rooms were exposed behind walls and under courts of later construction. In 1932 and 1934 some work had been done on these and four distinct types

of superstructures had been found in stratigraphic position. For description of the several types of superstructures see [Chapter 28.12].

The program for 1935 called for further investigation of the remains of the older buildings, and search for the nucleus from which the Palace started. It was also hoped that the pottery found in association with the various periods of construction would amplify, and serve as a check upon, the Uaxactún ceramic sequence that had been built up as result of the Institution's previous excavations. Work progressed satisfactorily. A wide trench, cut through the north side of the Palace at ground-level, gave access to the Buried Court, facilitating removal of dirt and providing an excellent cross-section of the building.

By the end of the season a number of rooms had been cleared, a new buried pyramid had been uncovered, and the whole northeast and part of the northwest corner of the Period III substructure were exposed. This very impressive platform proved to be faced with well-cut stones laid up on a batter and to rise, with the interruption about midway of a narrow terrace, to about 22 feet [6.7 m] above the level of the East Court. Its two exposed corners are inset and rounded. The platform supports another low platform which in turn supports eight Period III rooms.

The masonry of the various types of substructure proved to be of great interest and much was learned regarding the quality and amount of lime cement used and as to fills interpolated between binding layers. Rough walls, it was found, were built within the hearting to keep the fill in place during construction, and wooden beams were placed horizontally in the fill as an added support. Substructures were carefully observed in relation to their superstructures. Substructures, like superstructures, changed in their type of construction, the succession being in general from large rough stones laid horizontally and deeply set into the hearting, to thin veneers of well-cut blocks. With further investigation it should be possible to establish a definite correlation between superstructure and substructure masonry so that if only one is visible the type of construction used in the other would be known without excavation.

To date, 62 rooms, 14 buried rooms, five shrines, two buried shrines, four courts, one buried court, three dated stelae, and various caches and burials have been found in the Palace.

During the past season, 23 burials came to light. These were of all types and all periods and ranged from adults of both sexes to babies. There was one instance of a mother with fetal child. The positions of the skeletons varied from fully extended to closely flexed. Imprints of the fabrics used to wrap the bodies were found in several cases in the dried mud on the

walls of the burial chamber. The graves varied from well-made vaulted rooms, containing a great many offerings to simple holes in the fill below room or terrace floors. The mortuary pottery is, as a rule, of a more advanced type than that represented by the sherds in fills of the same period; many pieces of local manufacture are represented. In this one seems to see a predilection in funerary practice, for novelties and imported wares. Much whole pottery and great quantities of sherds were recovered, which are now being studied in Guatemala City. This work has not been completed, but it may be said that the sequence of types so far found in the Palace follows that previously established at Uaxactún. The two most interesting and beautiful vessels were a red barrel-shaped vase on an annular base, carved with four seated human figures in full costume; and a cylindrical vase of polished black ware covered with a thin coat of plaster upon which a series of figures is painted in pastel shades and with the delicacy and sureness of line characteristic of the finest codex painting. In a cache was found a set of nine obsidian flakes skillfully incised with figures of deities. Such objects have hitherto come to light only at Tikal. From all the evidence so far recovered from the Palace it would seem that the function of this complex building probably changed during the long period of its use. There are strong indications that during its last phase it served as living quarters as well as for religious ceremonies. It has been suggested that the purpose of structures of this type was to house priests and acolytes. They were also undoubtedly used as store houses for the elaborate paraphernalia, connected with the many ceremonies carried on throughout the year.

During 1934 most of the superstructure of Temple A-XVIII was excavated and mapped. In 1935 this work was completed. It is an 18 room building, two stories high, standing on a large platform. The upper story is reached by an interior stairway. The exterior was decorated with 14 large stucco masks set in panels. An interesting find made in A-XVIII was three-quarters of a bow which the Department of Agriculture of Guatemala identifies as the wood of the guayacan or cortés negro tree.

In Group B the excavation of Structure B-XIII was continued. This one-story building is of two periods and has many architectural features of interest.

In the course of remapping Group B, Mr. Shook discovered two large artificial reservoirs. One of these lies west of the causeway joining Groups A and B and the other is southwest of the Main Plaza of Group B, from which it received the drainage. Group B is built on a natural hill which has been leveled in some places and built up in others. A possible ballcourt was located; only slight excavation will be necessary to determine whether or not it is such.

There is fairly good evidence of two roads, one from west and one, from the north, leading into Group B. These are artificially leveled, areas extending out into the bush. They are comparable to the entrances into an Indian town of today, where the paved streets run a short distance beyond the town and, there join the trails and rough roads of the surrounding country. There is no evidence at Uaxactún of any such long and well-made highways as the *sacbé*s of Yucatán.

Material was gathered for an attempted time-correlation, by means potsherds, of the various major groups of structures at Uaxactún. Robert Smith carried on this work by means of test pits in plazas and trenches into mounds. At the end of the season a preliminary survey was made of a new group (H) discovered about 225 yards [205.7 m] south of Group E. It consists of two separate plazas surrounded by mounds of size.

28.15.

A. LEDYARD SMITH

Uaxactún

YB 35:115–117, 1936

The eleventh season at Uaxactún opened on February 29 and closed on May 30, with A. Ledyard Smith in charge, Edwin Shook acting as assistant and surveyor, Sr. Federico Soberanis as Guatemalan Government inspector. Practically the whole season was devoted to excavations in Structure A-V, the so-called Palace. Work on this multi-chambered building was begun in the spring of 1931 and has been continued during the past four winters. Statements regarding the archaeological significance of Structure A-V and accounts of earlier work are contained in [Chapters 28.11 to 28.14].

By the close of the 1934 season the outer parts of A-V had been cleared and evidence of earlier buildings found. In 1935 some of the older construction inside the Palace was uncovered and a wide trench, cut to bedrock, was run through the north side of the building to the Buried Court. The program for 1936 called for completion of the investigation of the Palace. It was hoped to trace the various periods of construction in the Palace from the nucleus from which it started, through to its last addition. To this end two more wide trenches were cut through the building, one east and west, the other north and south. So heavy a schedule

necessitated the employment of double the amount of labor used in previous years. The two large trenches, carried down to underlying limestone, completely transected the Palace. Two excellent cross-sections of the whole structure were thus obtained, which show plainly the method by which it was gradually built up.

First, the very uneven surface of the limestone was leveled by cutting away or filling in. In some instances the rock was cut to form the lower part of a terrace wall. The earliest floors were then built. The first floor, close above bedrock, supported a low, plastered, oval platform with a step at one end. Although no post holes were found, there can be little doubt that it once supported a house of perishable materials. On floors above this there came to light several fragments of similar platforms, one complete example 5 feet [1.5 m] above the bottom. It was oval in shape with a rectangular front terrace. The floor of the higher oval section was pierced by four post holes, the terrace by two, showing definitely that it once supported bush house. Using the original post holes, Mr. Smith made a reconstruction of the house. Two graffiti of bush houses supported by similar platform from a door jamb of one of the Period II rooms, served as a guide for restoration.

Above the house platform the type of construction changed. The floor directly overlying it supports the earliest truncated pyramid with vaulted superstructure. Following this there is a sequence of buildings showing gradual development both in substructures and superstructures, the most marked change having been from the use of large, roughly cut stones laid horizontally, to the production of true cut-stone veneer. For description of the several types of superstructures, see [Chapter 28.12]. The various building levels were clearly evident, and stratigraphic collections of sherds were gathered from each. These have not yet been studied, but they appear to confirm the ceramic sequence so far established for Uaxactún. It was of interest to find that polychrome wares first occur in the Palace in connection with the earliest vaulted buildings.

Much new archaeological information accrued. It was learned, for example, that the earliest terraces supporting stone buildings possessed rounded, inset corners similar in shape to those used in the next-to-last period. Another interesting discovery was of certain re-used stones, perforated and originally T-shaped. These resemble stones forming the roof decoration of a building represented in fresco in Room 37. One new buried room, one cache, two animal burials, and 20 human burials were found. The graves were of particular interest in that they were of all periods from earliest to latest, and varied greatly in construction.

The face of Stela 26, bearing the well-preserved and very early date 9.0.10.0.0, was cut from the monument and shipped in two fragments to the National

Museum in Guatemala City. For further information concerning Stela 26 see [Chapter 28.13].

In addition to the work on the Palace, the small reservoir east of the causeway joining A and B Groups was partly excavated, the causeway was investigated, and the ballcourt in B Group was uncovered. The reservoir lies about 100 feet [30.5 m] west of the causeway. It is rectangular, measuring 42 [12.8 m] by 48 feet [14.6 m], long axis east and west. In its construction the natural clay had been dug out to a depth of about 8 feet [2.4 m] at the center and gradually sloped up to the surrounding ground level. The bottom had then been covered with a 3 inch [7.6 cm] deposit of sand supporting a complete pavement of large stone slabs. These in turn were covered by an 8 inch [20.3 cm] layer of sand. Around the edge was a row of stone slabs placed horizontally. The reservoir, in a slight hollow, obtained the drainage from the higher ground in the immediate vicinity.

A trench was dug into the west side of the causeway connecting A and B Groups. The retaining wall was found to be so badly fallen that it was impossible to tell whether it had been vertical or sloping. The plastered floor of the causeway was then examined. It proved to turn up to parapets proximately 3 feet [91 cm] high on both sides of the causeway.

The ballcourt in B Group, lying at the north end of the causeway, is formed by two parallel rectangular structures, their long axes north and south. The intervening space is 14 feet [4.3 m] wide and 57 feet 6 inches [17.5 m] long. Of the two plastered floors discovered, only the upper has so far been red. This turns up on either side of the court to vertical, stone veneered. It is 2 feet [61 cm] high. From the tops of the walls terraces 13 feet [4 m] wide slope and 4 feet [1.2 m] to meet the 3.5 foot [1.1 m] vertical veneered walls of the upper terrace, which drops down vertically on the outside to plaza level. No markers were found in the alley or on the terraces, but such may occur when the upper floor of the alley is removed. This ballcourt is almost identical to one investigated by the University of Pennsylvania at Piedras Negras.

The large reservoir west of B Group was bushed, and a pit dug in its north side exposed a retaining wall. Much more work will have to be done before definite results can be obtained.

28.16.

A. LEDYARD SMITH

Uaxactún

YB 36:135–137, 1937

After 12 seasons of intensive investigation, the Division's activities at Uaxactún were brought to a close on May 15, 1937, and the camp and permanent equipment were turned over to the Government of Guatemala. Originally selected by Dr. Morley for excavation because, on the basis of its dated monuments, it was both the oldest and the longest inhabited of Old Empire Maya cities, Uaxactún has paid consistently, rich scientific dividends. Work there is now being terminated not because the site is even approaching exhaustion, but in order to allow Mr. Smith and his associates to bring up to date their studies of, and publications upon, the large collections and the abundant data already recovered. And it seems probable that when these tasks have been accomplished problems will have been formulated which will call for comparative research at other sites rather than for further work at Uaxactún.

Discovered by Morley in 1916, Uaxactún was revisited by him for epigraphic study in 1921 and 1922. In 1923 its geographic position was ascertained by W. A. Love, of the Institution's Department of Terrestrial Magnetism, and in 1924 F. Blom and W. M. Amsden mapped the site in preparation for the opening of excavations by O. G. Ricketson in 1926. The first five seasons were devoted to stratigraphic study of the early pre-stela deposits in Group E and to clearing various surrounding structures, the most important of which was the excellently preserved Pyramid E-VII Sub [Chapters 28.3 to 28.15]. During these years, all monuments at Uaxactún were carefully examined for sub-stela caches, and squeezes were made of the best-preserved monuments.

In 1931 activities were shifted to Group A, where, during the past seven years, the major part of the work has been concentrated on Structure A-V, a large and long-occupied palace type complex which contained invaluable stratigraphy, both ceramic and architectural. Also wholly or partially excavated were Structures A-I, A-II, A-III, A-XV, and A-XVIII, and a most important rubbish heap rich in pottery was discovered. A reservoir west of the causeway connecting Groups A and B was examined, as well as several structures in Group B, the most interesting of which were a ballcourt and Structure B-XIII. Testing was done in Groups C, D, and F, and in 1935 a new group, H, was discovered south of Group E.

During 1937 the investigation of Structure A-V was completed by determination of certain hitherto unascertained building sequences, and by collection of several pottery samples to check against those of previous years. Structure A-XVIII was further examined, its substructure being found to consist of three terraces. A trench into the south side of the building through the central doorway revealed, in the terrace in front of the doorway, an incised pottery vase surrounded by four eccentric flints and three eccentric obsidians, and containing two jade beads, two jade ear plugs, and a jade idol 10 inches [25.4 cm] high, weighing 11.5 pounds [5.2 kg].

Structure A-II was excavated because it is associated with the two latest dated monuments at Uaxactún Stela 12 (10.3.0.0.0) and Stela 13 (10.0.0.0.0). It proved to be the latest type of building so far uncovered at this site. What little of its superstructure remained showed that on its east side it had five doorways separated by masonry piers, the only example of this arrangement found at Uaxactún. The breadth of the temple's single room and the paucity of fallen masonry indicated that it had been roofed with beams and mortar or thatch, probably the latter.

The excavation of Structure B-XIII, begun in 1935, was sufficiently advanced to prove that it had undergone several reconstructions, all of Period I masonry, and that some of its rooms once supported beam and mortar roofs. On the back wall of one of these rooms was a well-preserved fresco depicting a small unvaulted building, within, in front of, and behind which are many elaborately garbed figures apparently engaged

in a ceremonial. Below the main part of the fresco is an alignment of 72 day signs in consecutive order starting with 12 Imix and ending with 5 Eb. Many of these glyphs present hitherto unknown variants of recognized forms. Sr. Antonio Tejeda, staff artist in Guatemala City, made a special trip to Uaxactún to copy the fresco.

Structure B-XII, a two-room building north of B-XIII, was of interest in that, although it is of Period 1, its vault approaches the later type which utilizes well-shaped bevel-faced stones rather than flat uncut stones. This would suggest that vault construction was beginning to be refined before veneer stones were employed in the walls of buildings.

Other work in Group B was an unsuccessful search for markers in, and for a possible earlier structure below, the ballcourt excavated in 1936. Investigation of the causeway connecting Groups A and B revealed an earlier causeway below the one studied in 1936. It differed from the latter in its lack of a parapet and in that its sides rose in two terraces. Ceramic evidence connects the early causeway with Period 1 construction.

Structure E-X was further examined. The three rooms of this well preserved building were cleared in 1927. During the past season it was discovered that these three units were originally a single long room. On the roof was uncovered a roof comb, a single long, narrow chamber, its back wall resting on the back wall, its front wall on the capstones, of the room below. This produced a frontal terrace. Access to the roof comb was gained by two narrow elbow-shaped passages through the capstones of the lower vault.

29.0. ZACUALPA

Robert Wauchope spent two months of excavation at Zacualpa for the Carnegie Institution of Washington in 1935. His investigation established the first archaeological sequence based on stratigraphy and comparative typology for this region of the central highlands of Guatemala. Wauchope returned in 1947 for another brief field season. The results were later published by the Middle American Research Institute at Tulane University.

29.1.

ROBERT WAUCHOPE

Zacualpa

YB 35:128–130, 1936

Investigations at Zacualpa, in the Department of Quiché, were carried on by Mr. Wauchope from No-

vember 27, 1935, to March 5, 1936. Mr. A. L. Smith and Dr. Ricketson accompanied him on preliminary trips to Zacualpa early in November and the Chairman spent two weeks there in February.

The excavations were undertaken at the suggestion of Dr. S. K. Lothrop, who visited the place in 1933, and who has in press a publication on the results of his study of collections made by "pot-hunters" in this and other parts of the Department. The most significant of the pottery and artifacts described by Dr. Lothrop are believed to have come from two tombs at Zacualpa. It was hoped that additional material would be obtained through excavation. The project fell in line, also, with the Division's general program for an archaeological survey of the Guatemala highlands.

The season's work consisted of: 1. Excavation of Group C, an assemblage of low mounds located on the terrace thought by Dr. Lothrop to have contained the looted tombs; 2. Excavation of a pottery-yielding section of the barranca which cuts into the north margin of Group A; 3. The drawing of a plane-table map of all

mounds in that part of the Zacualpa valley known as La Vega. During his two week visit, the Chairman made further examination of the barranca, excavated a cache of vessels in a low terrace between Groups A and C, recorded all artifacts for the forthcoming publication on Zacualpa, and collected surface sherds from mounds in the vicinity of La Vega. On their preliminary visit to Zacualpa, Messrs. Smith and Wauchope mapped a small group of mounds on the plateau across the river west of the modern town. In April Mrs. Ricketson began a study of the ceramic material recovered.

Group C lies on a terrace near the southwestern margin of the valley; it comprises several, long, low, rectangular mounds surrounding a small plaza. Three of these were excavated.

C-I, at the north corner of the terrace, exhibited five periods of growth. The first construction in C-I was probably the earliest in Group C, for the assemblage of its three small platform substructures and the manner in which rubbish had accumulated around them, indicate that they formed an independent nucleus from which the group of mounds later developed. Although the pottery has not yet been fully studied, the apparent absence of Plumbate Ware and animal-head legs from the first three periods of C-I, and their occurrence in all phases of the other mounds, confirm the architectural evidence. The outstanding pieces found in this mound were a large polychrome jar containing a cremation and some finely carved bones; a large incensario with spiked rim, twisted handles, traces of blue paint, and a well-molded human head with applied necklace, ear-plugs, and forehead decoration of intertwined serpents.

From the general appearance of the pottery, artifacts, and building construction of C-I, it seems likely that the platforms were for ceremonial use, while a series of adjacent rooms, which presented corresponding periods of occupation, were residential. The unit may have been the home of a person of consequence for it was more pretentious than the average house-mound and was advantageously located not far from the three main ceremonial centers of the city.

C-II, at the west corner of the terrace, also presented five periods of development. This mound again afforded excellent opportunity for stratigraphic study and yielded a far richer collection of ceramic material. The deposits of the earlier periods were marked by thick charcoal-bearing rubbish deposits, while those of later periods contained five cremations, four of which had been deposited in jars. These conditions suggest that C-II in its earliest stages was a house site with rubbish dump, which was burned and subsequently used as a crematory cemetery. The late intrusive cremation at C-I was probably contemporaneous.

The ceramic material from C-II presents a few outstanding features: abundance of Plumbate Ware of sev-

eral types, and of a finely (tuff?) tempered orange ware; several types of animal-head legs of the rattle type, probably mold made; fragments of two perforated incensarios and two painted jars, one of which bears a design recalling the dragon motif of Coclé, Panama.

C-III, facing the plaza from the southeast, had been much damaged by "pot-hunters"; four periods, however, could still be identified. Features of this mold were a looted tomb with walls of stone masonry; stone pavement and well-constructed terraces of stone on the northwest side; three large terrace postholes, in one of which the point of a main post was still preserved; clay floor-drains and a stone sub-terrace gutter, the latter graded and with a right-angle turn toward the plaza; a large unslipped brown ware jar containing several pounds of clay prepared for potting. C-III yielded, in addition, 10 complete vessels, five burials and four cremations.

Two interesting architectural features were common to the three mounds in Group C: adobe clay floors and wall plaster thoroughly burnt to a brick-red color; multiple pits in the adobe-clay floors. The function of the pits is unknown.

All cremations at Group C post-dated the inhumations.

The collection of artifacts from Group C is featured by an abundance of chipped obsidian points, obsidian flake-knives, polished green stone celts, clay fire-dogs, manos, and metates. Examples of other types of artifacts characteristic of the Guatemala highlands were perforated stone hammers or digging stick weights, green stone figurines, jadeite beads, a corrugated bark beater, worked sherds and sherd spindle-whorls. Set side by side in the clay plaza floor between C-I and C-II were a human figure of stone and a clay tiger head.

Among the objects from the barranca at Group A were about 40 complete vessels, a dozen green stone figurines, many jadeite beads, and two clay earplugs. The barranca pottery together with 12 vessels removed from two caches half-way between Groups A and C was quite distinct from that of Group C, the absence of Plumbate Ware, finely (tuff?) tempered orange wares, and animal-head legs, and the occurrence of certain Petén-like shapes and painted decorations suggesting the probability that it was older. Although few traces of bones were found in either of the two latter excavations, it is probable that they were grave caches.

A type of pottery common to all three localities and found on the surface throughout the valley is the "duck pot," a curious inverted vessel-shaped object with a handle and animal head at the top.

Out present knowledge of Guatemala highland archaeology does not permit very definite conclusions regarding the excavations at Zacualpa. There is as yet

so little to which the Zacualpa material may be compared or to which it may be contrasted, that we must be content to regard the season's investigation as part of the groundwork on which future conclusions are to be based. In general the pottery gives an impression of lateness, with foreign affiliations chiefly southern. Plumbate Ware, the Coclé-like design already mentioned, and small bowls supported on three tall legs reminiscent of Costa Rican forms, are among the outstanding examples to be cited.

Certain forms, however, resemble pottery from Teotihuacán, while bowls with basal flange and one polychrome sherd from the barranca seem to indicate

that Petén influence was also felt during an earlier period at Zacualpa. Figurines were scarce, "Archaic" forms apparently absent, and with the exception of Red on Buff scroll-decorated bowls, the painted wares were probably all importations. The general run of paste and slip was inferior. The only other decorative feature that seems typical of Zacualpa, and this only at the barranca and the mid-valley caches, consists of shallow vertical flutings often found in sets of three or four on the sides of shallow, straight-sided, dark brown and black ware bowls. To the above characteristic ceramic features should be added the particularly well-molded animal-head legs of Group C.

30.0. HONDURAS

30.1.

GUSTAV STRÖMSVIK

Honduras

YB 40:292–295, 1941

The work of excavation and repair at the ruins of Copán, Honduras, which has been in progress since 1936, was continued during the past winter. Mr. Strömsvik was assisted by Mr. Robert F. Burgh, Mr. Arthur W. Wheelwright, and Mr. Leonard J. Currie. The major activities of the season were completion of repair of the two temples at the Ball Court, and re-setting of the upper elements of the Jaguar Stairway. Mr. Burgh accomplished a thorough survey of the minor ruins in the valley. As in former years, the Government of Honduras cooperated most effectively, providing all labor, including five master masons specially sent to Copán, and transporting, without cost to the Institution, supplies from the railhead at Chiquimula in Guatemala.

The temples at the Ball Court were large and handsome structures with elaborately ornamented façades flanking the two sides of the court's playing alley. Their massive vaults had collapsed, filling and covering the lower parts of the several chambers of each temple with stone and rubble. In 1940 this was cleared away

and the still standing outer walls were solidified by the method developed by Messrs. Morris and Strömsvik in their work on the Temple of the Warriors at Chichén Itzá and followed in all subsequent repair operations. Solidification is made necessary by the fact that the original adhesive qualities of the ancient lime or mud mortar have more or less been destroyed through action of percolating rain water, with such weakening of the masonry as to render walls incapable of standing for any length of time, once the supporting debris has been withdrawn. In such cases a wall is cleaned and photographed, and the cut stones of the outer veneer are numbered and removed. If the hearting is found in bad condition, it also is taken down and rebuilt with fresh lime mortar; but if sound, it is allowed to stand and the facing is relaid in cement, each stone occupying exactly its original position. Finally, the wall is capped with cement to prevent further entrance of water.

During the past season the inner walls of both temples were accorded the above treatment. Of the East

Temple, the south end, including the vaults of the south and southeast rooms, was rebuilt to its former height. This restoration was particularly desirable, as no example of the interesting and highly typical Maya corbelled vault remains standing at Copán. It was possible because the original stones, though fallen, were still available; and it could be done with confidence, as a sufficient number of the lowermost stones of the vault were found in place to allow accurate calculation of their angle and height.

The wide doorways of this and other Copán temples had been spanned with heavy beams, whose decay, incidentally was one of the major factors in bringing about the collapse of the upper walls. In the restoration, the lintels were made of reinforced concrete cast to the size and shape of their wooden prototypes. The façades over each doorway had been decorated with sculptured panels representing a gigantic and highly conventionalized parrot with protruding head and claws. Since the depictions had been composed of dozens of relatively small carved stones tenoned, like a mosaic, into the wall, and since these elements had been broken and scattered when the façades fell, and some had been carried away in recent times, the correct reassembling of the panels was so uncertain that the spaces occupied by them have, for the time being, been left vacant. The stones have been carefully numbered and preserved, however, and it is possible that further study will result in a satisfactory solution of this oversize jigsaw puzzle.

The West Temple was cleared and its walls reset as high as the second course above the medial molding. Farther up it was not possible to go because this temple, lying nearer to the road than does its mate, had largely been robbed of cut stone for use in building the modern town of Copán.

In connection with the work on the temples, the badly displaced facing of the terraces and steps surrounding the north end of the Ball Court proper was taken down and relaid. This produced a proper setting for Stela 2, which stands upon the north platform, and links the latter with the structures bordering the whole complex. Also, to the south of the East Temple, the lowest terrace of the high Pyramid 26 was rebuilt, thus making clear the relation between the Hieroglyphic Stairway, mounting that pyramid, and the Ball Court. During this operation there were recovered and replaced certain hitherto missing elements forming the base of the Hieroglyphic Stairway's north balustrade.

A second major undertaking was concerned with the Jaguar Stairway in the East Court. The lower part was repaired in 1938, but this increased the necessity of completing the construction, including the magnificent Venus mask panel (so-called because of large hieroglyphs of that planet on either side of the mask).

The task involved the removal of the existing remains, the building of a solid masonry foundation, and the replacement of the upper terraces, the stairs, and the mask itself.

While work was under way in the East Court, opportunity was taken to repair the vaulted drain which runs eastward under Mound 19 and opens on the river front. Former excavators had dug a large cut into the mound, causing a serious cave-in of the fine example of Maya vaulting in this drain. The interior was rebuilt, and the steps of Mound 19 were replaced as far as possible without reconstructing the whole stairway.

In 1939 some inscribed stones came to light around the roots of the giant ceiba tree, standing on the east end of the mound of Temple II; on further investigation blocks forming an almost complete hieroglyphic panel were extracted from beneath the enormous tree. This panel, from the north side of the east entrance, corresponded in size to others previously known to flank either side of both the north and south doorways of the temple. During the past season search was made for the companion panel at the south side of the east entrance. It was found partially crushed, but all pieces were present, constituting the only complete hieroglyphic panel recovered from Temple II. This structure had four doorways, each framed by two panels, each panel containing from 15 to 18 glyph blocks. Thus the eight texts comprised about 140 glyph blocks, many more than any other temple in Copán can boast. For this reason it has been decided to call it "The Temple of the Inscriptions." The panel found in 1939 was removed to the Copán Museum, as it could not well be replaced, without destroying the giant ceiba; the one discovered this year was reset in its original location.

In 1940 the opening of a drain was found under the west end of the Acropolis. This solved the puzzling problem of how disposal, had, been effected of the great amounts of water which fell each rainy season on the Ceremonial Court, the Middle Court, and the Court of the Hieroglyphic Stairway. This season the drain was excavated, with great difficulty as it measured only 45 by 50 cm and was completely full of hard-packed refuse. It proved to have been built of three tiers of well fitted masonry, laid on a paved floor, and covered with wide capstones. Several of the latter, had broken and tipped downward into the drain, further hampering the work of clearing it. A stoppage had taken place at the far end, apparently when the west side of the Acropolis fell into ruin, and most of the many potsherds found in the passage occurred there; among them was a complete water jar shaped much like those used in the valley today. The caved-in entrance of the drain was repaired, and the outlet cleared to permit free flow for the water that has hitherto accumulated in the Court of the Hieroglyphic Stairway.

During the digging of the escape ditch through the high pile of debris fallen from the Acropolis, two skeletons were encountered, both apparently of young men. Although the bones were in the last stages of decay, the teeth were well preserved; the six upper front teeth of each skeleton were inlaid with jade.

Repairs were made of several sculptures: fine double-headed monster at the west end of the Court of the Hieroglyphic Stairway, Altars H' and I' at the south of the West Court, and Altar G in the Ceremonial Court.

Mr. Burgh devoted the major part season to completion of the map locating the outlying ruins of Copán. The area covered was about 18 sq km, within which the ruins, the Copán River, minor drainages, roads, and settlements at shown at a scale of 1:10,000. Control established by a system of triangulation on the higher hills, and a number of the stations were marked by permanent stone monuments. The meridian was determined by astronomical observations, the datum by barometric readings. Mapping of ruins was done with a plane table. The majority of the sites were pyramids, terraces, and courts bordered by mounds; the rest were clusters of small mounds. All sites, however small, were drawn to scale and the various types are identified by conventional signs on the map. Sites were numbered serially within the areas designated by Dr. Morley (1920, Plate 3).

Six ruins were mapped at a scale of 1:500, with a contour interval of 0.5 m. No excavation was attempted at these sites, save at no. 2 in area 9, where a large, handsomely cut stone in the center of the court was overturned to ascertain whether hieroglyphics were present on any of the buried faces. None was found.

Sketches at a scale of 1:1,000 were made of 26 ruins, with cross sections and notation of the presence or absence of cut stone and sculpture.

The commonest type of outlying structure at Copán proved to be a court bordered by mounds on three, or sometimes on all 4, sides. No system of orientation was evident. Apparently these sites were residential, the mounds, rubble-filled and faced with cut stone, serving as platforms for dwellings. They are not all contemporaneous, and as it is likely that some of the larger mounds served for many consecutive occupations, they may be expected to show many alterations and enlargements. Occasionally, a single large mound was accompanied by many lesser ones, perhaps platforms for smaller houses.

There were several unusual structures. The great court of Ostuman, about 2.5 km west of Copán Village, was doubtless a complex of religious structures. To judge by the absence of sculpture, it was earlier than the Main Group. On El Plan de las Mesas, a high hill northwest of Copán, are several structures of curious shape built of roughly quarried stone. The most west-

erly is a round tower, 8 m in diameter and 1.5 m high. One fragment of rude sculpture suggests a later date than the primitive masonry would imply. Just 0.5 km east of the Main Group, in the midst of a dense cluster of plazas and mounds, there is a causeway about 10 m wide throughout its length and about 1 m high. If this was a roadway to the Main Group, as seems likely, there is no positive trace of its westward extension.

It cannot be assumed that sites with roughly hewn stones are earlier than the others, because it is possible that they represent the rubble interior of mounds from which the better-cut stones were removed for use elsewhere.

Excavation was done at Site 8:16, a refuse area in a gully east and north of Stela 6. No house remains were encountered, but occupational debris was found, its maximum depth being 2 m. Two levels of occupation were in evidence. The upper, a mixed stratum varying in depth from 20 to 50 cm, was contemporaneous with the Old Empire remains in the Main Group. In this level were three burials, all badly decayed. Between the upper and lower levels was a thick white deposit, the remains of a plastered courtyard, or perhaps a house area from which the stones had been removed for use elsewhere. The lower deposit had a maximum depth of 1.5 m. It apparently long antedated the upper level, as the pottery was of early types, much with "Usulután" (wax process?) decoration, chiefly on tetrapod plates. Sherds of ollas were characteristically ornamented with a band of clay pinched on around the girdle. A few sherds of stuccoed ware were found. Hundreds of small incense burners, 6 to 8 cm high, came to light, whole or fragmentary. They were decorated with punctate designs. Most surprising was a sherd of polychrome ware at the bottom of the deposit, 2 m below the surface. It was red and black on yellow, and technically superior to any of the later wares. Snail shells occurred by the thousand, and there can be no question that this was a kitchen midden.

30.2.

GUSTAV STRÖMSVIK

Honduras

YB 41:249–259, 1942

As in former years, the activities of the Copán Expedition, a project sponsored jointly by the Government of Honduras and Carnegie Institution, comprised both

repair of buildings and excavations with purely archaeological objectives. Mr. Strömsvik was again in charge, assisted by Mr. Douglas Elliott and Sr. Jesús Núñez, the latter completing the Spanish catalogue of the large collection now housed in the Copán museum.

The work of preservation was concentrated on the Temple of the Inscriptions (Temple II), which in its day was perhaps the most imposing of the many elaborately adorned buildings of the Acropolis, as it dominated both the Court of the Hieroglyphic Stairway and the West Court. In previous seasons much repair had been carried out on the temple proper, and the great range of steps mounting to it from the Court of the Hieroglyphic Stairway had been cleared of debris and its upper parts consolidated. Much remained to be done, however, on the other side, where the stairway rising from the West Court to the first platform and that from the platform to the temple were badly broken down. Also, the seven terraces flanking the stairways had been so badly warped and the masonry so skewed by the enormous weight above them that it was deemed advisable to take them down stone by stone and rebuild them. As has always been Mr. Strömsvik's practice in such work, the areas to be dismantled were carefully surveyed and photographed, and each stone numbered before removal. Study of the plans and sections made clear certain previously unknown features of construction, and there came to light, during the removal of fallen material, a number of fine sculptures fallen from the western and southern façades of the temple. In addition to the resetting of the western stairways and terraces, the south side of the temple substructure, the east half of the south stairway, and the southwest corner of the temple were rebuilt.

In former years the East Court had been entirely cleared, save for a great pile of fallen masonry in the northeast corner. This pile not only detracted from the appearance of the court, but offered the only hope of recovering sculpture from Temple 20, the greater part of which had gradually been eaten away as the Copán River, before its diversion, cut into the Acropolis. The heaped debris was cleared away, the excavation bringing to light materials which proved that the entire west façade of the temple had fallen forward onto its frontal stairway. From the heap came several hundred pieces of carved stone, among them some of the finest yet found at Copán: geometric elements, grotesque animal and human forms, dozens of Ahau faces of various sizes, and many finely sculptured human heads, from half natural size to as much as 0.8 m high. These showed such great individuality as to suggest that they were portrait studies. There were also recovered more fragments of the large bat figures found earlier at the edge of this heap. It is thought that the bats were roof ornaments, standing free atop the west façade.

Most of the above-mentioned sculpture is now arranged in rows along the steps of Temple 20; certain outstanding pieces have been moved to the Museum.

Another phase of preservation work was the solidification of the tunnel under the Temple of the Inscriptions, about 30 m of which were lined with lateral masonry walls and roofed with a corbeled vault, to guard against possible cave-ins and leave the tunnel open for inspection by students and visitors who may wish to see the many interesting superimposed constructions that went into the building of the Acropolis. Minor tasks were the repair of a large jaguar sculpture on Platform 20, which now lacks only the head and the feet on the left side; and the setting upon a solid base of the gigantic head at the northeast corner of the Temple of the Inscriptions.

The more strictly archaeological work of the season was largely confined to digging in search of burials, and stratified rubbish deposits in the vicinity of the Acropolis. During the rainy season of 1941 two burials had been washed out of the riverbank 200 m south of the Acropolis. Following this lead, a trench was run west from the bank, revealing an extensive and long-used cemetery. In the excavation of no more than 150 cubic meters of earth 25 burials were found, from close to the surface to a depth of over 3 m. Three distinct strata were found from close to the surface to a depth of over 3 m. Three distinct strata were recognizable: the uppermost assignable to the late or Great Acropolis period; the to the first or Early Acropolis period; the lowest, in which hardly any cut stone was found, to the pre-Acropolis period. Although most of the burials combined no mortuary offerings, some were provided with pottery vessels and jade, shell and clay ornaments. About 50 pieces of pottery, whole or repairable, were recovered. Most of the skeletons were so rotted that only the teeth could be preserved. A number of these were inlaid with jade. Burials of the three periods may be characterized as follows:

Late or Great Acropolis Period: Bodies usually placed flexed in rectangular masonry cists of well squared stones; inlaid teeth common; great variety of pottery types, shapes, and colors; polychrome abundant; Copán adaptation of Usulután Ware; Yojoa Ware appears; great quantities of the small, crude votive vessels usually called *candeleros*. Tentative dates for this period: 9.10.0.0 to 10.0.0.0 in the Maya time count.

First or Early Acropolis Period: Bodies laid flexed in open ground, occasionally in burial cists of cut stones; inlaid teeth present; Polychrome and "Copán Red" pottery appear; many basal-flanged bowls; Copán adaptation of Usulután style common; Incised Black Ware common; carved slab-legged cylinders with lids; many *candeleros*. Tentative dates: 8.15.0.0 to 9.10.0.0.

Pre-Acropolis Period: Three skeletons found, all extended; two in crude oval burial cists of uncut stones, and river boulders, roofed with large unshaped slabs; length of skeletons as they lay in the ground: 1.61, 1.62, and 1.63 m; no inlaid teeth; pottery: Red on Buff, ring-base bowls with red trim, true Usulután plates with large bulbous legs, Red on Cream effigy jugs, carved slab-legged cylinders with lids; many candeleros. Tentative dates: ? to 8.15.0.0.0.

Metates without legs and with tapering handstones were common in all three strata, as were clay griddles.

During the season the museum catalogue was greatly amplified; many fine sculptures were repaired and placed on exhibit; and five new showcases were installed, containing pottery, ornaments, and skeletal material, among which is a complete skull with inlaid teeth, of the Early Acropolis period.

30.3.

GUSTAV STRÖMSVIK
Honduras and Guatemala

YB 48:231–232, 1949

During the past season no archaeological excavation took place at Copán, but an experiment in preserving archaeological sculpture should be recorded. Sculpture that has lain in the ground for some time is subject to minute plant growth, such as lichen and fungus, whose roots loosen the tiny particles of the surface of the sculpture; rain and wind continue the erosion. The sandstone at Quiriguá and the tuff at Copán are particularly liable to this action. Some years ago Sylvanus G. Morley sprayed Stela K at Quiriguá with a hardening agent, but the monument is again covered with lichen and fungus. Early this season Mr. R. E. Smith sent a new hardening agent to Copán for experimentation. The six lowest steps of the Hieroglyphic Stairway were carefully cleaned and dried; the viscous fluid was then applied with a brush. It will be some years before the results can be seen.

Progress was made toward completing a report on the three superimposed ballcourts at Copán [Chapter 31.4]. Considerable work also was done in amplifying, checking, and correcting the specimen catalogue at the Copán Museum as a preliminary step in the

preparation of a report on the cultural material in the Copán Valley.

In March, Strömsvik went to Guatemala for consultation with the Chairman of the Division. About this time, near the town of Asunción Mita, Department of Jutiapa, several mounds of ruins were in danger of being razed by the construction of the Roosevelt Highway, whose route lay directly across the biggest and most important mound, locally called Cerro de Laja. Strömsvik consequently went there at the beginning of April to obtain all possible information before the mounds were destroyed and to cooperate with the Institute of Anthropology and History of Guatemala, which defrayed half of the costs and supplied the services of Sr. Gustavo Espinoza, who assisted most ably in the excavations and explorations.

At the Cerro de Laja, which was our chief concern, a room filled with debris was completely excavated in order to examine the structural and architectural details, particularly the vaulting. This is the southernmost occurrence of the vault so far found in the Maya area. There can be no doubt, moreover, that the structure is of Mayoid origin, for numerous fragments of Maya Polychrome and Copador pottery were found in the debris, thereby placing the remains in the Classic period.

There undoubtedly are other rooms in this large mound, which will soon be removed completely by the highway work. At that time the details of construction should be recorded as they become apparent.

The countryside surrounding Asunción Mita was given a hasty reconnaissance: Brunton compass survey maps were made of four main ruins and some minor ones. The main groups were designated A, B, C, and D (Cerro de Laja is Mound 1 in Group A). In Group A lies the best-preserved ballcourt, from which were removed two parrot-head sculptures now to be seen in the entranceway of a house in town. These heads, like those at Copán, were cut to stand vertically in the benches. Another less well preserved ballcourt is located in Group C, west of the road and uphill from Group A. Groups A, B, and C are located south of town, between it and the bridge of Tamazulapa. All appear to be more or less of the Late Classic period, in part contemporaneous with the Acropolis at Copán. These groups consist mainly of small courts each dominated by a larger structure. All constructions, of mud and slate on lava-block foundations, are oriented roughly to the cardinal points. Another type of construction seen in these groups is the tombs, of which there seem to be a great many, both sacked and untouched. All are vaulted.

Group D is located 1 km due north of town. It consists of a number of round, much eroded mounds, irregularly placed one, built of mud with very little

admixture of river boulders and no slate. Wherever a road cut through a mound, potsherds were gathered. These proved to be of Usulután Ware and decoration, very similar to ceramics of the Miraflores phase in the Guatemala highlands. No polychrome pottery was recovered at Group D.

There apparently was a pre-Columbian settlement just where the town of Asunción Mita is now located. We were told by inhabitants that whenever one digs artifacts turn up. A typical stone "yoke" and some pottery showing accentuated phallic symbols have been found here. Mexican affinity is suggested, and one wonders if the remains may be Pipil.

In reviewing the findings at Asunción Mita and vicinity, we seem to see three phases of occupation: 1. A population of Mexican stock apparently resided here at the time of the Spanish conquest, how long is unknown. 2. There was a Classic Maya phase of unknown duration, contemporaneous with one phase at Copán, when Copador pottery spread over parts of Honduras and El Salvador. That was the high point in the Maya culture. 3. There apparently also had existed an earlier settlement, characterized by earth mounds and Usulután pottery, and probably contemporaneous with the Miraflores phase in the Guatemala highlands.

31.0. COPÁN

Copán is one of the most extraordinary archaeological sites in Mesoamerica. The Carnegie Institution of Washington carried out an ambitious excavation and restoration program at the site from 1935 to 1946, except for the years when work was suspended because of World War II. Work at Copán was undertaken with two objectives: repair the stelae, other monuments, and the best-preserved buildings to protect them from disintegration; to gain, in the course of this repair, all information possible regarding the history of the site. The Honduran government supplied all labor and materials for the repair work and defrayed the costs of incidental transportation. It purchased the land enclosing the Main Group of ruins and established it as a national monument, employing workers year around to keep the site bushed and in good repair. The CIW supplied the technical staff and directed the course of excavations. Hieroglyphs were documented, the stelae were repaired and uprighted where needed, some of the architecture was restored, and many tombs were excavated. Perhaps one of the most beneficial endeavors was the rechanneling of the course of the Copán River, which prevented further destruction of the site. Be-

ginning in the mid-1970s work at Copán has been continuous. In 1975 Gordon R. Willey of Harvard University went to Copán to design a long-term program of research and restoration to be sponsored by the Honduran government; in 1977 Claude F. Baudez, of CNRS, directed the first phase of the project. In 1980, William T. Sanders and David L. Webster, both of Pennsylvania State University, directed the second phase, and in 1985 the Copán Mosaic Project, directed by William L. Fash, of Harvard University was begun. Extensive excavations have been carried out in the Acropolis in a project involving Fash and Ricardo Agurcia Fasquelle of the Instituto Hondureño de Antropología e Historia, Robert J. Sharer and David Sedat, and E. Wyllys Andrews V. In 1980 UNESCO declared Copán a World Heritage Site.

31.1.

SYLVANUS G. MORLEY

Copán Expedition

YB 25:277–282, 1926

Toward the end of March, Dr. Morley left Chichén Itzá for Guatemala by way of Veracruz and the land route down the Pacific Coast. He was accompanied by Joseph Linden Smith, the artist, and Robert A. Franks, Jr., as assistant. John Lindsay, a field observer of the Department of Terrestrial Magnetism, joined the party at Guatemala City on April 3, and the following week all proceeded to the ruins of Copán in western Honduras.

The object of this expedition was to check the accuracy of previous observations on the Copán astronomical base-line, a line of sight running east and west across the Copán Valley connecting two of the hieroglyphic monuments, the so-called Piedras Pintadas, Stelae 10 and 12.

These two monuments stand on opposite sides of the valley, 4.1 miles [6.6 km] apart in an air-line; the western one, Stela 10, on the crest of a hill 2,779 feet [847 m] above sea-level, and the eastern one, Stela 12, well down on the side of, an even higher hill, at an elevation of 2,553 feet [778.1 m] above sea-level.

Because of the fact that it had been erected on the crest of a hill, and not on the side, and also because it is slightly higher than Stela 12, Stela 10 practically stands clear against the horizon, or very nearly so, as observed from Stela 12. And since the bearing of the line between these two monuments is almost east and west, it has long been suspected that some sunset observation had formerly been made from Stela 12 looking toward Stela 10.

From observations made for the Institution at Stela 12 on March 8, 1916, by Arthur Carpenter, data were secured which were interpreted by Professor R. W. Willson, of the Harvard Astronomical Department, as indicating that the sun set behind Stela 10 as observed from Stela 12, 20.3 days after the vernal-equinox and 20.6 days before the autumnal equinox, that is, that the sun set behind Stela 10 as observed from Stela 12 twice a year, once on April 9, on its apparent march north, and again on September 2, on its apparent return south. Both these monuments have Initial Series dates inscribed upon them, and Stela 12, a Period-Ending date as well (Table 31.1.1).

Dr. H. J. Spinden (1924:134–135) in his work on Mayan dates, wherein he has attempted to establish a day for day correlation of Maya and Christian chronology, has reached the following Gregorian equivalents for these three dates (Table 31.1.2).

Table 31.1.1. Calendrical Decipherments, Copán.

Stela 12		
9.10.15.0.0	6 Ahau	13 Mac
9.11.0.0.0	12 Ahau	8 Ceh
Stela 10		
9.10.19.13.0	3 Ahau	8 Yaxkin

Table 31.1.2. Correlation of Maya and Christian Calendars.

9.10.15.0.0	6 Ahau	13 Mac	January 11, 388 AD
9.10.19.13.0	3 Ahau	8 Yaxkin	September 6, 392 AD
9.11.0.0.0	12 Ahau	8 Ceh	December 15, 392 AD

He further supposes that the line of sunset originally established by Stelae 10 and 12 fell on September 6 and its reciprocal, April 5, and that later this line was shifted presumably by moving Stela 10 to the north so as to mark the line of sunset on April 9 and September 2, the dates indicated by the Carpenter observations in 1916. He argued that September 6 might have had a ceremonial importance in connection with the planting of the second crop and therefore called it the first position of the autumnal station, while September 2 was called the second position of the autumnal station. It was pointed out that the four day change may have been made to affect a coincidence with the closing day of Katun 12. The first autumnal date September 6 is recorded on Stela 10 and on Altar U; the second autumnal date, September 2, is recorded on Altar U in striking combination with its reciprocal April 9, and is reached by the famous 6 Caban 10 Mol, which is of more frequent occurrence than any date at Copán. The association of these dates on Altar U is [shown in Table 31.1.3].

To these coincidences was added the fact that the Initial Series of Stela A declared April 5, the reciprocal of September 6.

It had become a matter of considerable importance therefore the exact azimuth of the line joining Stela 10 and Stela 12, which with the other data, such as the exact latitude and longitude of Copán; length of the line of sight, and relative elevations of the two monuments, would determine the exact dates the sun would set behind Stela 10 as observed from Stela 12.

Through the kindness of the Director of the Department of Terrestrial Magnetism and of Dr. Fleming, John Lindsay, a field observer of the Department, was detailed, with all the necessary instruments, to accompany Dr. Morley to Copán and to make check observations on this supposed astronomical base-line. The party reached Copán on April 6. The first task was the clearing of the crest of the hill where Stela 10 had formerly stood, and the re-erection of that monument as nearly as possible in its original position. The former

9.16.12.5.17	6 Caban	10 Mol	September 2, 503

position of Stela 12 on the eastern side of the valley was also prepared for the observations, and a bench mark established where it had stood for future reference.

Solar observations were made on April 9, 10, 12, 13 and 14, 1926, at Stela 12. The latitude and longitude at this stela and the azimuth of the line joining Stela 10 and 12 were determined by repeated observations. The direction of the sun's path was also determined on the above dates and enough data secured to determine the exact position of the sun at sunset, as viewed from Stela 12 on any day. It appears from the final calculations, that the sun would set behind the mountain, which lies behind Stela 10 as seen from Stela 12, and exactly on the line extended between these two monuments, on April 12, 1926.¹

The following summary of Mr. Lindsay's observations on the astronomical base-line at Copán has been prepared by the Department of Terrestrial Magnetism:

1. So near as can be determined from the observations and from independent calculations depending upon the geographic position of Copán, the sunset on April 12, 1926, was behind Stela 10 as observed from Stela 12, the local time of the sunset behind the low ridge being 6 h 07 m which is in good agreement with the results obtained from Mr. Lindsay's graphs. At this time of year and for the approximate latitude of Copán, the sun sets about one minute of time later each day.
2. Assuming the length of line between Mound 3 and Mound 16 to be 960 feet [292.6 m] as taken from the surveyed maps by A. P. Maudslay and G. B. Gordon, then the air-line distance between Stela 10 and Stela 12 is 21,734 feet [6,624.5 m]. Of course, this distance will be affected by the same percentage of error as the assumed base, namely, 960 feet [292.6 m], may be.
3. The distance between the point at the center of the sun's disk at the time of setting on April 11 and at the time of setting on April 12, as measured along the crest of the hill where the western monument stands, is 135 feet [41.2 m].
4. Apparently on April 12, 1926, the sun set almost exactly behind Stela 10 as viewed from Stela 12, that is to say, its center was practically over Stela 10, when it sank behind the low ridge a mile [1.6 km] or so beyond Stela 10.
5. From measurement of vertical angles, Stela 10 is 226 feet [68.9 m] higher than Stela 12. Referring to publication 219 of the Carnegie Institution it is noted

that from data given this difference in elevation would result as 129 feet [39.3 m], since the elevations above the plaza given are Stela 10, 228 m, and Stela 12, 188.6 m, a difference of 39.4 m; the difference in elevation as determined from vertical angles should, of course, be much more nearly correct.

6. Assuming that the point on the church spire at Copán sighted upon by Mr. Lindsay in measuring the vertical angle from Stela 12 is about 70 feet [21.3 m] above the plaza, it appears that Stela 12 is 595 feet [181.4 m] higher than the plaza; thus the height above sea level of Stela 12 may be reckoned as 2,553 feet [778 m], whence from the data given under 5. The elevation of Stela 10 above sea level is 2,779 feet [847 m].
7. The difference in elevation between Stela 10 and Stela 12 as indicated by a single aneroid reading by Mr. Lindsay at each point is 292 feet [89 m].
8. The distances determined from the triangulation using as a base the length of line between Mound 3 and Mound 16 as 960 feet [292.6 m] are as follows: Stela 12 to church in Copán, 6,352 feet [1936.1 m]; Stela 10 to church in Copán, 15,558 feet [4742.1 m].
9. The geographic coordinates as determined from Mr. Lindsay's observations are [shown in Table 31.1.4]. And the azimuth of the line from Stela 12 to Stela 10 is 98 degrees 51'.0 west of true south.
10. The values of the magnetic inclination, and declination, were determined on Mound 3 at the Main Structure, the declination being 7 degrees 10' east and the inclination 42 degrees 26' north.

These results, although they differ by three days from those derived from Mr. Carpenter's observations made just 10 years ago, agree with those made by Dr. Gordon more than 30 years ago, and should be accepted as correct. Mr. Lindsay, in addition to being a highly trained observer with an exceptional field technique, had the advantage of a complete outfit of instruments, theodolite, chronometers, aneroid barometers, boiling-point apparatus, etc., and the data he gathered may be accepted as final.

There is evidence that Stela 10 may have stood 4 feet [1.2 m] south of its present position, though this is not sufficient to throw the sunset along the line extended by Stelae 10 and 12, as much as a single day earlier, i. e. back to April 11 or forward to August 31. The artificial terrace upon which this monument was erected is 72 feet [21.9 m] long north and south, and 50 feet [15.2 m] wide east and west, but instead of standing

Table 31.1.4. Geographic Coordinates of Stelae 10 and 12, and Church, Copán.

Point	Latitude North	Longitude of Greenwich
Stela 10	14 deg. 51'.0	89 deg. 08'.1
Stela 12	14 deg. 50'.4	89 deg. 04'.5
Church	14 deg. 50'.7	89 deg. 06'.4

at the middle of its long dimension, that is, the middle of this terrace as viewed from Stela 12, Stela 10 is 8 feet [2.4 m] nearer the northern end than the southern end, that is, it is 4 feet [1.2 m] north of the middle point.

Calculations made at the Department of Terrestrial Magnetism indicate that in order for the sun to set on April 9 along a line extended by these two monuments, as used by Spinden in his correlation, it would be necessary to shift Stela 10, 405 feet [123.4 m] south of its present position, which shift would carry it completely off the terrace built to support it and on to the rough crest of the hill.

The best explanation of the line extended by these two monuments appears to the writer to be the following, though definite proof thereof lacking. It is the general custom in western Honduras at the present time to burn off the fields some time early in April to clear them for planting at the beginning of the rainy season, a month later. It is certain, that after burning had once been started, no sunset observation on Stela 10 would have been possible from Stela 12. Such was the hazy, smoke-laden condition of the atmosphere from April 9 to 14 of the present year at Copán, that even with a high-powered telescope it was impossible to see Stela 10 from Stela 12 at sunset, and without any instrument of precision it would have been even more hopeless. Indeed, the only way it was possible to secure the azimuth of this line was by erecting behind Stela 10 an enormous pile of fat-pine faggots, 16 feet [4.9 m] long and 10 feet [3.1 m] high, and setting fire to it at night. This caused such an illuminated field behind Stela 10 that, even in spite of the heavy pall of smoke overhanging the valley, it was possible to see the monument outlined against this illumination and to secure the azimuth of the line.

The writer believes these two monuments were erected in the positions which they now occupy in order to coincide with the line of sunset on April, and further, that this was the day which the priests at Copán had selected for the formal firing of the fields, since an earlier burning would have given time for bush to have grown up again before the advent of the first rains early in May when planting could be begun; and finally when in the course of its progress north, the sun having at last sunk behind the western hills at a point directly above Stela 10 as observed from Stela 12 (that is, on April 12), then, but not until then, were the ancient inhabitants of Copán and its environs permitted to burn their fields against the fast approaching rainy season. In short, it appears probable that these two monuments were a giant gnomon, which marked for the inhabitants of the city the position of the sun on the day which their ritual indicated as that upon which their fields should be fired, that is, made ready for the coming planting season; or, as Spinden has not

unhappily named it, "the beginning of the agricultural year," which for Copán at least, judging by the observations made this year, would seem to have fallen on April 12.

Spinden has recently advanced significant arguments tending to show that April 12 was the emphatic position of Venus in the natural year, reached in various calculations, and that this date pairs with August 30 which is also prominently declared. The Initial Series on Stela A at Copán give 9.14.19.8.0, 12 Ahau 13 Cumhu, April 5, 471. This not only gives the reciprocal of September 6 but it also coincides with an inferior conjunction of Venus with the sun. The heliacal rising of the planet occurred four days later on April 9; and 0 Pop, the Maya New Year day, took place three days after this on April 12. At the height of the Great Period 9.15.10.0.0 equaled August 30, 481, and fell in a year when 0 Pop was April 9. Moreover at Tikal this date is emphatically associated with April 9 perhaps to emphasize the shift that is being made. Also, 9.19.0.0.0, 9 Ahau 18 Mo is only one day less than the reciprocal of April 12, being August 29. Finally on Stela F at Quiriguá the certain dates refer to the revised base line. These can be arranged as [in Table 31.1.5].

Here the 19 year cycle of Meton is used to give the same place in the natural year and the same phase of the moon between the first two numbers and it may be added that 0 Pop was April 9 in 480 to 483 and April 5 from 496 till 503.

The three readings by Gordon, Carpenter and Lindsey of the azimuth of the line connecting Stelae 10 and 12 have a considerable divergence, Lindsey's being 23' greater than Gordon's and 38' less than Carpenter's (Table 31.1.6).

Then there is the tilting of the line which is neglected in Professor Willson's interpretation and possibly certain other minor elements.

It is becoming increasingly apparent, and very largely through the Institution's investigations, that astronomical considerations influenced the placement,

that is, the positions, where the Maya monuments were erected; and that in many cases they were used as giant gnomons for marking specific lines of sight establishing specific astronomical phenomena. So fruitful, indeed, has this line of investigation proved in the past three years, as for example Frans Blom's discoveries in regard to the lines of sight extended by Stelae 18, 19, El and 20 at Uaxactún in 1924 [Chapter 28.1], and the discoveries of O. G. Ricketson, Jr., in the Caracol at Chichén Itzá in 1925 [Chapter 38.6], that it is confidently anticipated further study in this particular direction will be richly repaid.

NOTES

1. More than 30 years ago Dr. G. B. Gordon, in charge of the Third Expedition of the Peabody Museum of Harvard University to Copán, had reached the correct azimuth of the line extended by Stelae 10 and 12, giving the day April 12 and its reciprocal August 30, the same pair reached by Mr. Lindsay this year (Morley 1920:133–134).

31.2.

GUSTAV STRÖMSVIK

Copán

YB 34:118–120, 1935

The work at Copán in western Honduras was undertaken, in cooperation with the Honduran government, for two purposes: to repair and protect the remarkable stelae and other monuments for which these ruins are famous; and to secure data bearing on fundamentally important problems of Maya sculpture, architecture and ceramics.

Copán is a classic site for Maya archaeology. It was first brought to general notice by Stephens' and Catherwood's pioneer investigations; Maudslay's unrivaled photographs and drawings of the Copán sculptures, made in the [18]80s, gave tremendous impetus to Maya research; in the [18]90s nine extensive excavations were carried on at Copán by the Peabody Museum of Harvard University; Spinden based his great work on Maya art very largely upon the Copán carvings; and Morley made its inscriptions the subject of the first of his exhaustive epigraphic monographs. In spite of so much activity, neither the "dirt archaeology" of Copán itself nor the relations of the city to

other centers of Maya development is adequately known, for the work of the Peabody Museum was done before the introduction of modern methods of excavation, and both Morley and Spinden confined their studies to single aspects of culture. The current project should therefore result in accumulation of many significant new data. The first year was devoted primarily to such repairs as were most urgently necessary; reassembly and re-erection of the many broken, fallen and, leaning stelae; and preliminary steps to prevent further destruction by the Copán River of the enormous mound known as the Acropolis.

Mr. Strömsvik, assisted by Mr. Deric Nusbaum, was in the field from January to June, inclusive. Equipment, tools and food-supplies were bought in New Orleans and shipped through Guatemala by rail to Chiquimula, whence they were transported across the mountains to Copán by the Government of Honduras.

Actual work started on January 15th. The ruins, being completely overgrown, had carefully to be cleaned before an adequate idea could be formed as to the number of damaged monuments which required attention. Timbers for tall stout scaffoldings were assembled, and Col. Antonio Sans, paymaster and representative of the Government arrived with two picked masons. By the end of January the repair was well under way, starting with Stela 4 in the Great Plaza, a monument very badly broken by its fall and repeated milpa fires.

An excavation was also started under the base of Stela A, on the east side of the Plaza. This stela was leaning so badly, apparently as result of a recent severe earthquake, that it was in danger of falling, as were Stelae H and P. One of the first steps was therefore to secure these stelae without stout wooden braces until they could be straightened and their bases strengthened. Earthquakes occurred almost daily, in stronger and weaker degrees.

In order to straighten a stela, the butt must be freed on all sides to allow it to be restored to vertical position without undue strain upon the tall stone shaft. In such clearing of their bases excellent opportunities were afforded for study of the manner in which stela had originally been erected, and for observations of the cruciform offertory chambers usually found beneath them. Eighteen stelae were thus examined for dedicatory offerings. These proved, for the most part, to consist of pottery vessels, the majority of crude ware, a few of finer workmanship. Other objects found in the cruciform vaults were seashells, coral and disintegrated cinnabar. Probably the most important discovery of the season was the finding, under Stela H, together with some broken beads of jade and other stones, of two tiny gold fragments, the legs of a small hollow figurine, which in complete state perhaps

served as a pendent to a necklace formed by the beads. That most of the latter were in pieces seems to indicate that they were broken ceremonially before being placed under the stelae, as most likely was also the gold figurine. Thorough, but unsuccessful, search was made for the rest of the figurine. The bits recovered are the first objects of gold which are definitely assignable to the Old Empire period.

Research upon the specimens, particularly those of pottery, found in connection with the Copán stelae is outstandingly important, because of the fact that these monuments bear hieroglyphic dates which permit them to be ranked in chronological order. And, when the correlation question has been settled, we shall be able to place them in terms of the Christian calendar. Thus the sub-stela objects, already serialable relative to each other, and doubtless eventually even datable, provide valuable materials not only for determination of the nature and the rate of Maya culture growth, but also through comparative study of trade-specimens, to establish cross-links between certain stages of Copán culture and developments in other areas, within and without the Maya field.

Several trenches were dug in the Great Plaza to define relations of the stelae to the plaza levels, and of the latter to surrounding structures. Many potsherds and fragments of implements came to light, as well as a cache of several hundred large obsidian blades.

Other activities of the 1935 field season were restoring of a partly destroyed burial chamber in the East Court, the only accessible roofed structure in the ruins; the laying out and partial supervision of the clearing and leveling of a new flying field, near the ruins; and the fencing of the entire Government reservation, both ruins and flying-field, to keep out cattle and unauthorized visitors. A number of altars and sculptured stones were repaired and examined for ceremonial offerings; and those that had been moved in recent years were restored as nearly as possible to their original positions.

Much thought was given to ways and means of preventing the Copán River from cutting farther into the high bank forming the east side of the Acropolis. Since Maudslay's time, some 50 years ago, the river has eaten away a strip approximately 10 m thick by 100 m long, reaching from the base to the top of the Acropolis, a height of 35 m. The remnants of two richly sculptured structures have been lost, and much destruction is threatened. The cut made by the river forms at present the most spectacular and instructive archaeological cross-section in the Maya area. The problem of guarding the Acropolis from the assaults of the small but intermittently raging river proved a difficult one. Many plans were formed and discarded, such as building a solid breakwater the length of the exposed

face, or chaining a floating protection of boomed logs along its front; but the expense of importing the necessary large quantities of cement and iron was found to be prohibitive. It was finally decided to adopt the radical expedient of changing the course of the river by opening a ditch across a tongue of land to the east. This will bring the channel, straight down the valley, some 100 m away from the ruins. It is thought that a relatively small canal will serve to start the river on its new course, and that it will do most of the necessary digging itself.

31.3.

GUSTAV STRÖMSVIK

Copán

YB 35:117–120, 1936

The current field-season at Copán comprised the months of December 1935 to May 1936, inclusive. Mr. Gustav Strömsvik was in charge, assisted Mr. Aubrey S. Trik. Col. Antonio Sans, representative of the Honduran government, most efficiently and tactfully handled the employment labor and the transportation of supplies. Principal activities were diversion of the Copán River, tunneling into the Acropolis, mapping the Acropolis, and repair of Temple 22.

Of most immediate practical importance was the turning of the Copán River away from the site. For centuries this stream, subject to violent minor floods, has been undermining and washing away large parts of the ruins. The most evident damage has been caused to the enormous central group known as the Acropolis, as is proved by early Spanish accounts and by the photographs and plans of Maudslay and the Peabody Museum made 50 and 40 years ago, which show that the Acropolis formerly extended considerably farther to the south.

The problem of protecting the Acropolis was studied during the 1935 season, and it was decided to open a canal across an ox-bow bend, throwing the river, by means of a diversion dam, into this new channel. The canal was accordingly dug by Government labor, under supervision of Colonel Sans in the summer of 1935.

To haul the large quantities of rock required for the dam a specially equipped dump truck was shipped by sea to Puerto Barrios, by rail to Zacapa and thence driven to Copán. No motor car had hitherto penetrated this part of Honduras and the last 25 miles [40.2 km]

over mountain mule-trails necessitated five days of unremitting toil. A mile [1.6 km] of road was then built up the river to the dam-site, a loading hopper was constructed, and work was begun on the heaps of uncut stones and *débris* left by earlier excavations. Some 7,000 tons of this material were thus clear from the Court of the Hieroglyphic Stairway and put into the dam. Early in March the water was turned into the canal, but the heightening and thickening of the dam continued until the end of the season. It remains to be tested by the floods of the coming summer.

Extensive tunneling operations were conducted in the Acropolis as a first step in the study of this vast complex which, like so many Maya constructions, grew to its present size by the piling of building on building clear evidence that the Acropolis contains a number of accretions is offered by the cut made by the river on its eastern face, where a whole series of earlier floor levels and several sections of masonry wall have been exposed. It was therefore certain that an extensive stratigraphy of architectural remains must lie within, and it was hoped that well-preserved buildings might perhaps be found, as has been the case at Chichén Itzá and at Uaxactún.

Toward the close of the last season Tunnel I was started in Mound 11, at the side of Stela N in the Court of the Hieroglyphic Stairway. An underlying stairway was immediately encountered, only 2 m below the outer stairs. The solid adobe and stone fill of the structure rendered tunneling comparatively easy and safe. Lack of proper digging tools, however, and particularly of means for lighting and ventilating the work rendered continuation in 1935 inadvisable. This year a small electric plant was imported to supply light and, by means of fans, to insure circulation of air. Work on Tunnel I was continued, and another, Tunnel II, was opened into Mound 26, beside the foot of the Hieroglyphic Stairway. Tunnel I was run up the 19 steps of the buried stairway, along a low, terrace and up several more steps, upon the highest of which was found an as yet undeciphered hieroglyphic inscription 2 m long. The tunnel was driven to the very center of the mound, where the difficulty of disposing of the *débris* became so great that it was temporarily abandoned.

Tunnel II was dug through the talus of *débris* at the base of the mound, through two courses of the facing masonry of the lowest outer terrace, and into the hearting of the pyramid. The first few meters consisted of rough quarried stones set in adobe mixed with lime. Then the basal courses of an earlier pyramid were found. The faced-stone covering, if such had existed, had been removed. The fill of this older, construction, contained more and purer adobe and fewer stones; the latter, for the most part water worn boulders, were laid in regular horizontal courses between thick layers of

adobe. The tunnel was continued until a cross-wall of small, roughly faced stones was encountered, some 10 m from the outer terrace. Following up this wall toward the south, a badly defaced and chipped stucco mask panel was found, adorning the side of a low terrace. Further digging proved that the upper part of this terrace had been mostly removed before being covered over. A downward-sloping drift was then started, going under the base-courses of the terrace, in search of still earlier constructions. It was run inward and down through the above-mentioned adobe and river-boulder fill, eventually reaching a thin layer of black, sticky, contained potsherds, charcoal, and animal bones. Beneath this midden was virgin soil.

When Tunnel I had been completed, a new one, Tunnel III, was started to the east side of Stela N, and pushed straight into the mound, through the stairway followed in Tunnel I. It penetrated three superimposed stairways, eventually reaching a very flat stairway; this was followed upward in the hope of finding a hieroglyphic inscription similar to that laid bare in Trench 1; the top step, however, was plain. Valuable series of potsherds and numerous small artifacts were gathered from the various levels. A pit sunk through the innermost and lowest structure found in Tunnel III, which is a low terrace under Stair 4, revealed several floor-levels. Virgin soil was reached at about the same depth as in Tunnel II. None of the potsherds from the pits or tunnels, even those from beneath the lowest floors, appeared to be typologically more archaic than those from the source; the ceramic material, however, has yet to be examined by a specialist. At present it therefore seems probable that the site of the Acropolis and adjacent mounds was reclaimed from the river and the enormous mass of construction erected in a comparatively short time. To accomplish this the population of the vicinity of Copán must have been large. It seems reasonable to believe that the ancestors of the builders of the Acropolis must also have lived in the valley; some presumably on the higher land, here the remains of their settlements should have escaped destruction by the floods which seem periodically to have swept the lower-lying terrain. When these have been found, materials of great importance should accrue.

A third activity was the beginning of a detailed map of the Acropolis and adjacent structures, a project undertaken during January and February by Edwin Shook before he left for Uaxactún. Mr. Shook not only surveyed such parts of the ruins as remained uncovered by *débris*, but also made a number of minor excavations to determine the location of mound and plaza corners. A number of interesting sculptures were thus brought light.

Reconstruction was confined entirely to Temple 22. This most beautiful of all Copán buildings, located

on the north side of the East Court of the Main Group, has been gradually falling to pieces due to the action of vegetation and weather; and in December 1934 a heavy earthquake reduced it to a shapeless mound.

Work was begun by Mr. Trik in December by clearing away the trees and brush which were beginning to envelop the ruin. Excavation was started at the entrance of the temple. Only a few courses of the jambs were found in position, but the wall-stones were in place almost up to the spring of the vault. Although standing, the walls were leaning heavily and it was necessary to relay them in cement.

Practically all the carved stones in the sculptured decoration of the interior doorway, the outstanding feature of the building, had fallen. They had not suffered greatly and could largely be replaced in their original positions as shown in Maudslay's photographs. In reconstructing this sculpture the ancient method of supporting the stones and vault over the doorway became evident. This had involved the use of long wooden beams which fitted into specially cut stones and rested on the top course of the walls on either side of the doorway. The original beams had rotted, dropping the carved stones down on the wall, and giving a deceptive appearance that the stones were *in situ*. In rebuilding this portion of the Temple, Mr. Trik used two strong mahogany beams to carry the sculpture. The only lacking stones are those which spanned the actual opening of the doorway and a few pieces from the east side. It is possible that these may be found and the restoration of the sculpture be completed by further excavation outside the temple.

Attention was next turned to the elaborate decoration on either side the doorway. The east side of the façade was excavated, bringing to light unexpectedly large parts of the wall and of the flanking sculptures. Although the entire composition can not be restored, enough remains to show that a gigantic serpent head formed the entrance to the temple. The mosaic of carved stones on either side represents the eye and cheek elements, and breaking out from the wall on either side, is a large curling fang which rests on the upper step of the stairway. The face of the step is carved to represent the teeth of the lower jaw. The doorway, between the eyes and fangs, forms the mouth.

Few artifacts were found in Temple 22, but a great number of broken pieces of sculpture from an earlier structure occurred in the fill of the walls; practically all were painted a dark oxide red and several showed small patches of bright green plaster.

Mr. Trik devoted much time to study of the construction, plan and decoration of the building. Sketches illustrating structural methods were made, and measured drawings of the sculpture begun. From these architectural restorations will later be prepared.

31.4.

GUSTAV STRÖMSVIK

Copán

YB 36:137–139, 1937

The third season of cooperative work by the Government of Honduras and Carnegie Institution of Washington at Copán opened December 1, 1936, to take advantage of the full six months of dry winter weather. Activities of the year were further attempts to protect the ruins from destruction by the Copán River; study and repair of the Hieroglyphic Stairway; and completion of study and repair of Temple 22. As in former years, the Government has defrayed all costs of labor and of the transportation of supplies. Dr. Jesús M. Rodríguez, Minister of Public Education, under whose auspices the project is carried on, visited the site several times during the season for conferences with Mr. Strömsvik, Dr. Morley, and the Chairman. Dr. Rodríguez' unremitting interest in and support of the work have, not only been of great practical value but have also permitted personal contacts highly prized by the Division's staff. Thanks are likewise due to Colonel José A. Rivera, government representative at Copán.

In the struggle with the river, the dam which had been built in 1936 and later washed out by the summer floods was replaced by a longer dam reinforced by several hundred piles, and the diversion canal was widened and deepened. Signs of a flank attack by the rising waters of early summer were becoming evident when Mr. Strömsvik left Copán in June, and it is possible that complete diversion of the river may never be feasible. If so, protection by rip rapping will have to be afforded, the base of the Acropolis. It is imperative that this important structure be saved. Repair of the magnificent Hieroglyphic Stairway was begun. Dr. Morley, who was at Copán for a month in the late winter studying new epigraphic material, and assembling and arranging the fallen sections of the stairway preparatory to their replacement, reports that about 62 steps constituted the original flight. Only the bottom 15 were *in situ*. Fifteen others, however, had slid downward en bloc. These, excavated in the 1890s by the Peabody Museum of Harvard University and laid out in the plaza in their proper order, were replaced during the past season in the position which it is almost certain they had formerly occupied.¹

Discovery of a ballcourt between Structures 9 and 10 near the Hieroglyphic Stairway (tentatively dated by Dr. Morley at 9.17.4.0.0) was perhaps the outstanding event of the season.² It overlies two earlier ballcourts, the middle one possessing three finely carved,

circular stone "markers," the oldest showing traces of having had circular plaster "markers" decorated with paint.

Mr. Trik completed the excavation and repair of Temple 22, which he began in 1936. Last season, attention was devoted to the clearing of the mound and to reassembly of the interior sculpture. It was found that enough of the building was standing to justify continuation of repair, and to permit thorough study of one of the most important and most complete structures in Copán.

Work was resumed by clearing the north room of debris. The sculptured stones originally over the interior doorway were found piled in the room, where they had been placed by some earlier excavator and subsequently covered by falling walls. These stones completed the sculptured decoration of the room.

The west transverse room yielded information on vault construction. There a wooden lintel over a niche had rotted, allowing a large section of the vault to fall en bloc with the stones still in position, showing a fine construction of long, carefully fitted, corbelling stones. Exceptionally long-tenoned vault stones were found throughout the building, about 80 cm being an average, but some reaching a length of 1.3 m. The weakness of the vault was apparently in the lack of a strong binder rather than in the cutting and setting of the stones.

The ground plan of the temple was found to be quite different from any of the published plans in that the east and west rooms are not symmetrical, while the north room does not have the two narrow wings shown in all earlier plans. It was evident that the temple had never before been completely cleared, as niches in the north and west rooms, a passageway in the east room, and a dais in the west room had not been discovered.

Investigation of the base courses of the walls showed that its original design had been changed during construction and gave clear indication of the method followed in laying out the rooms when the building was begun. This was done by setting single courses of stones at about floor level, thus providing lines to be followed as the walls were erected. Where changes in plan occurred, such courses were covered by the new walls.

The platform on which the temple stands was cleared and repaired, and the stairway leading up to the platform was reset. This consists of eight steps about 8 m long and contains some of the largest stones used in Copán. Several are over 2 m long and weigh approximately a ton and a half.

Evidence that the temple had been used as living quarters after its abandonment as a ceremonial building was found in the form of occupational refuse. Dur-

ing the clearing of the rooms and terrace floor, numerous artifacts and pieces of sculptured decoration were encountered. Among these was a beautifully chipped obsidian ceremonial blade measuring 33 cm in length. The outstanding piece of sculpture was an unusually well-preserved head of the Singing Girl type, from the west side of the platform. It, with other similar pieces, formed a part of the façade decoration.

A study of the scattered sculpture was begun, particularly of such parts as could definitely be assigned to some part of the building. As no part of the upper zone was standing, this examination was limited to the elaborate masks on the four corners of the temple and to the large serpent mask forming the entrance. Unallocated stones were sorted and piled where they will be available for further study.

In connection with reconstruction of the Hieroglyphic Stairway, the summit of Mound 26, up which the stairway led, was investigated in order to find the level of the temple platform, as one check on the number of steps in the stairway. No indications of a building were evident until removal of surface debris revealed large, scattered fragments of a very thick, hard floor. By fitting these together, like sherds of pottery, most of the outline of a chamber was reconstructed. Its limits were clearly indicated by the turned-up edges of the flooring where it had abutted the walls, and the doorway was located by pieces which projected beyond the line of the front wall. Forty-four, beautifully carved stones were found. These had formed part of a four course frieze of full-figure glyphs, probably across the medial wall, two courses apparently in the wall and two in the vault. Two stones of the lower course had cord-holders, indicating that the band had been carried on wooden beams over an interior doorway. Some 70 similar stones from the slopes of Mound 26 are now in Peabody Museum and in Tegucigalpa. It is probable that they are part of the same frieze and that the assemblage can be completed. If so, it will constitute the longest inscription now known in the very rare full-figure hieroglyphs.

A small amount of digging was done on the southwest corner of the mound in order to locate the terrace walls. Four of the upper terraces were found and recorded and the excavations refilled as protection from further destruction.

NOTES

1. Dr. Tozzer kindly supplied copies of original notes and photographs from the files of Peabody Museum, without which this undertaking could not have been carried out.

2. Other new dates deciphered by Dr. Morley are: the step of Temple 11 (9.16.15.0.0) and Altar W' (9.18.0.0.0).

31.5.

GUSTAV STRÖMSVIK

Copán

YB 37:147–152, 1938

The fourth season of cooperative work by the government of Honduras, and Carnegie Institution opened December 1, 1937. Mr. Strömsvik, in charge, was assisted by Aubrey S. Trik and J. M. Longyear, the latter devoting himself to ceramic studies. Volunteer assistants were Miss Margaret Ennis, George E. Roosevelt, Jr., Donald Barrow, and Harvey Fite.

The work of protecting the main group of the ruins against further damage by the river is believed to have been brought to a successful conclusion during this season; the pole dam built in 1937 withstood the summer's floods, except for minor erosion around both ends during the peak of high water. As had been hoped, the diversion canal dug in 1936–37 was amply widened and deepened by the river itself and when the floods subsided the stream confined itself to its new course. By repairing and extending the pole dam and by building it much higher with stone and earth removed from the ruins it was greatly strengthened.

Mr. Strömsvik continued excavation and repair of the ballcourt discovered in 1937. Like other Maya ballcourts, it consists of a long rectangular playing area bounded on either side by a low vertically faced bench, from which sloping surfaces rise to a second vertical wall. The present court differs from other known examples in having been adorned with six monolithic parrot heads, three on either side (one at each end, and one at the center of the upper edge of the sloping surfaces). Although all six heads had been thrown down, the butt or tenon of the center head on the east side was found *in situ*, and the head at the south end of the west bench lay in such a position that its original location could be determined. These two heads were reset. They supply evidence which will permit eventual replacement of the remaining four.

On the east side of the court a narrow and much weathered hieroglyphic band runs upward from the center of the lower bench, crosses the sloping surface, and terminates at the central parrot head. From such glyphs as were legible Dr. Morley, in 1937, obtained a tentative reading of the date 9.17.4.0.0. In the course of this year's work it became necessary temporarily to remove one of the slabs of the band. It proved to be a reused stone from a similar, earlier band, doubtless belonging to one of two older, dismantled ballcourts found, in 1937, underlying the present court. The stone in question bore an excellently preserved and almost

complete Initial Series introducing glyph whose variable element represents the Venus sign, which, according to Dr. Morley, should only occur at 9.4.0.0.0, 13 Ahau 18 Yax, approximately 260 years prior to the apparent date of the latest ballcourt.

General repair of the ballcourt comprised re-laying the flat stones of the whole playing surface and parts of the sloping surface pavements, which had been forced out of level by pressure of tree roots; and rebuilding the vertical faces of the two basal benches.

Mr. Strömsvik also replaced certain elements of the Hieroglyphic Stairway and of its intricately carved balustrade, and made studies looking toward possible further reconstruction. To date have been added to what remained standing of the stairway only stones whose former position was known. Mr. Strömsvik, however, considers it advisable to complete the entire flight. Practically all the rest of the blocks are available, and although their exact original order will probably always remain uncertain, their resetting in the stairway would not only restore to this extraordinary construction its former impressiveness and beauty, but would preserve from damage the stones at present lying scattered in the court. Needless to say, the elements so reset would be so marked as to distinguish them, for students, from those found *in situ* and those regarding whose place there is no doubt. Mr. Trik devoted the season to Mound 11. This work was undertaken in order to preserve the remains of the temple and substructure, and to study the structure as an architectural unit in the complex of the Acropolis. The temple crowning the mound has undergone more or less excavation at various times since Maudslay's initial work there some 50 years ago. At the beginning of the 1938 season it was a tree-covered mound with little of the original construction showing through the vegetation and fallen debris.

The first consideration in the clearing of the mound was protection, from damage by material being removed from above, of the exposed sculpture of the Reviewing Stand at the foot of the south slope, and of Stela N and its altar at the base of the north side of the mound. The former was shielded by a covering of earth and stone and Stela N was guarded by erecting a barrier of poles halfway down the slope. Excavation was begun by opening a passage through the central chamber to the south doorway of the temple.

Clearing the center and west part of the interior of the temple revealed that on the north a gallery, about 30 m long, extends the full length of the building. There is a small central chamber, 60 cm above the level of the north gallery, and a small south vestibule on the same level as the north room. In the south wall of the north room, on either side of the central chamber doorway, are two stair wells. The west well was completely exca-

vated and reset to a height of eight risers. Although no part of the building exists above the spring line of the vault, it is certain that it formerly possessed a second story. This is indicated by the two stairways, by the massive solidity of the plan, and by the fact that the walls of the north room had been reinforced by two secondary walls about one meter thick, evidently built to help support the load imposed on the vault by upper construction too heavy for the original three meter span of the room.

In the floor of the central chamber an opening 1 m by 60 cm was found at the foot of the east wall. Débris and fallen wall stones had completely filled the opening, which proved to be the entrance to a shaft leading down into the substructure of the building. The shaft for 2 m down is constructed with three step-like projections and a narrow ledge, which reduce its size to about 75 cm by 40 cm. At the edge of the lowest projection it is enlarged to about 1.3 m by 65 cm, and the walls run vertically down for 3 m to a plaster floor. The masonry walls are built up from the level of the substructure and are an integral part of the temple construction. In the two side walls are pairs of post holes, probably used to facilitate descent.

Many human bones and teeth, as well as animal remains, were found mixed with the debris filling the shaft. At 25 cm above the floor fragments of two large stone incensario lids were found, one decorated with a hieroglyphic band. Enough pieces were recovered to enable Mr. Thompson to read the date as 9.17.2.0.0, 10 Ahau 8 Cumhu. Just below these fragments was a thin layer of earth mixed with ash and charcoal containing the remains of a scattered cache. Numerous obsidian blades, bird bones, human teeth, and sherds were found, as well as parts of a deer bone beautifully carved in low relief with human figures and a hieroglyphic inscription. The remainder of the cache consisted of several small shell beads, bone tools and a deposit of some vegetable fiber heavily coated with red pigment.

When the shaft was entirely cleared, a circular cut was found in the floor, the opening sealed with two rough stones. Below these were cached a small turtle carapace, two *Spondylus princeps* shells, and a rough, hard green stone.

The sculptural decoration within the temple comprises two hieroglyphic panels on the jambs of the north doorway, a highly conventionalized serpent mask framing the doorway to the central chamber, a similar mask around the opposite doorway of the same chamber, and two hieroglyphic jambs at the south doorway. A new inscription was uncovered at the west doorway of the north room. It had been concealed by the secondary construction and was badly scattered by the falling vault and walls. All the stones were recovered, however, and the inscription almost

completely reassembled. The date was read by Mr. Thompson as 9.17.0.0.16, 3 Cib 9 Pop. Although a great number of stones from the other panels were recovered, only a small part could be reassembled because certain necessary pieces have not yet come to light.

The walls and terraces of the substructure on the south side were cleared and solidified. This operation included repair of the Reviewing Stand, built out from the lowest south terrace. The stand consists of a flight of six steps, 16.3 m broad, leading to a battered terrace wall. The top step bears a hieroglyphic inscription flanked on either side by a kneeling figure holding a serpent in one hand and a scepter in the other. The steps were realigned, the inscription repaired, and the scattered parts of the figures reassembled the heads and scepters of both figures had been lost until this season, when excavation uncovered those of the west figure. The head is a magnificent example of stone carving, well preserved and of an unusual facial type. The parts of the east figure had been lying in the West Court, badly weathered, but had not previously been recognized as belonging to the Reviewing Stand.

An unusual feature of the substructure is a series of small rectangular niches, about 60 by 60 cm, built into the wall of the second terrace. Eight of these were excavated and repaired. Two were found to continue into the mound and to connect by a narrow passage. At either end of the passage is a small chamber about 1.3 m by 60 cm. The whole construction was originally capped with large stones, some measuring as much as 1.7 m by 0.5 m by 0.35 m. No indication of the use of the chambers was found.

The west side of the mound was excavated in order to check terrace levels and construction details. A stairway with a battered balustrade was found to lead to the west doorway of the temple. No repair was carried out on this side. On the north side only enough was done to recover the plan of the temple and to reveal the condition of the façade. Very little of the north part of the building remains.

Future work in the Mound 11 complex will be limited to solidifying the foundations of the temple on the north, now in very precarious condition, and to clearing the great stairway which descends on that side to the Court of the Hieroglyphic Stairway.

The Jaguar Stairway on the west side of the East Court was also repaired this season with the assistance of Mr. Harvey Fite of Bard College. This stairway, a secondary construction built over an earlier flight of steps, consists of a run of eight steps built out from a terrace wall which takes the form of a low bench about 1 m high, a setback 60 cm deep, and a battered wall 1.5 m high, topped by a wide vertical course. In the battered zone on either side of the stairway a large rampant jaguar stands in high relief from the wall.

Very little of the wall was found in position and the jaguars had completely fallen. Mr. Fite recovered all the parts and reassembled the figures in the wall, repairing the broken pieces with cement. The work was completed by resetting the terrace, and realigning the stairway. A portion of the north end of the terrace was left open in order to show the original construction over which it was built.

Mr. Longyear this year inaugurated at Copán a series of ceramic studies, which it is hoped may be extended to cover the southeastern part of the Maya area. The season's work was devoted to the pottery of Copán and included the digging of a number of test pits and trenches, as well as study of sherds and vessels recovered in past seasons while resetting stelae and running trenches into the Acropolis. Through the courtesy of Dr. Jesús María Rodríguez, Minister of Public Education of Honduras, Mr. Longyear was able to bring a large sample of sherd material to the United States for study.

Advent of the rainy season unfortunately ended digging before excavation of the earliest deposits was completed, but on the basis of present material, three ceramic periods can be recognized. In the earliest or Pre-Acropolis period, Usulután Ware, a type characteristic of the most ancient horizon so far identified in the highlands of Guatemala, and in Salvador, was introduced into Copán. Although Usulután constitutes a large percentage of the Pre-Acropolis pottery, there is evidence that this ware did not make its appearance until the latest phase of the period. The succeeding Acropolis period saw the decline of Usulután and the beginning and rise of polychrome pottery. The zenith of Copán ceramics was reached at this time, both in variety of types and in excellence of decoration. Carved Brown Ware and hematite redware are diagnostics for the latest phase of the Acropolis period. The last or Post-Acropolis period was represented by material from a dump lying on the surface of the Temple 22 pyramid. The sherds from this dump are unlike those found in the test pits and tunnels, being largely coarse-textured, thin-walled Utility Ware, and from their position above the latest floors of the temple, are believed to be the product, of people who inhabited the Acropolis after the decline of Maya civilization at Copán.

Connections between the pottery of Copán and that of other sites in the Maya area are as yet indefinite. A few specimens of late Ulúa Valley I and Lake Yojoa pottery were recovered in deposits of the Acropolis period, and Petén polychrome types seem also to be represented here, but very meagerly. More work must be done in the areas surrounding Copán before the latter site can be assigned its proper place in the Maya ceramic complex.

The dating of Copán pottery periods remains vague, for tie-ins between stratigraphical test-pit material and dated monuments and buildings have not yet been satisfactorily determined. At present it might be suggested that the Pre-Acropolis period goes back an indefinite length of time before the early part of the ninth cycle; that the Acropolis period runs from the early part of the ninth cycle to 9.18.0.0.0; and that the Post-Acropolis period follows that. The Acropolis period will almost certainly be subdivided after further digging and study.

Future work in this area should be concentrated on: a. A further study of Copán ceramics, embracing a search for both very early and very late types and the correlation of Copán types with dated monuments and buildings; b. Intensive research in Salvador on the problems of pottery sequences in that country and their relations with Copán and other areas; c. Investigations in Honduras to the east and north of Copán to determine the avenues and areas of contact between Copán and the Ulúa drainage.

31.6.

ALFRED V. KIDDER

Copán

YB 38:241–242, 1939

The Copán Project, inaugurated in 1935 and jointly supported by the Government of Honduras and the Carnegie Corporation, has had two main objectives: the clearing and repair of buildings and monuments, and the gathering of detailed archaeological data. The former is primarily a task of conservation: to make available for present-day visitors and scholars and to preserve for future generations the unrivaled architectural and sculptural treasures of this outstanding center of Old Empire civilization. The conservation work has naturally produced much new information regarding the antiquities of Copán and various supplementary investigations have been made for the purpose of studying special aspects of the ancient culture.

For several miles up and down the narrow valley of the Copán River are mounds strewn with cut stone and fragments of sculpture. These remains of the city's minor temples cluster most thickly about the Acropolis, a central dominating structure built up generation after generation by successive additions and enlarge-

ments until it became a huge and lofty complex of temple-pyramids, terraces, stairways, and courts. On the Acropolis, in a great plaza adjoining it, and at various smaller groups in the valley, stood the intricately carved stone monuments so typical of the greater Old Empire cities. The stelae and their accompanying altars bear the hieroglyphic inscriptions, the partial decipherment of which has told us practically all we know regarding the astronomical and calendrical knowledge of the Maya. Those of Copán are numerous and exceptionally fine, but, like the richly sculptured temples before which they stood, the stelae had for the most part been thrown down and shattered by earthquakes and the impact of falling trees.

The first season at Copán was devoted largely to the assembling, mending, and re-erection of stelae. During the second, exploratory tunnels were driven into the Acropolis to determine whether or not, complete buildings had been sealed beneath later accretions. This was often done by the Maya, but at Copán the tunnels proved that older temples were normally torn down before additions were made. Substructures, however, were found to have been left intact and valuable data were recovered regarding their nature and the successive stages by which the Acropolis grew to its present enormous size. Also in the second year, there was begun the excavation and repair of Temple XXII. This was probably the finest and is certainly the best preserved of the culminating buildings on the Acropolis. Work upon it was finished in the third season, during which attention was also given to the consolidation of the great Hieroglyphic Stairway and the excavation of an interesting superposition of narrow courts in which an ancient ceremonial ball game had been played. The fourth year saw further work on the stairway and ballcourts, but the major activity was the repair of a second temple, XI, together with the elaborate series of terraces leading up to it. From 1935 on there was a long struggle with the Copán River, which for centuries had been eating into the Acropolis. Finally, in 1937 Mr. Strömsvik succeeded in turning this seasonally rampant stream into a new course well away from the ruins.

Concurrently with the program of conservation there were carried on studies of architecture, sculpture, and pottery, which have yielded great amounts of data, intrinsically interesting and particularly useful for comparison with findings in other parts of the Maya area.

During the past season Mr. Strömsvik, assisted by S. Boggs, continued work on Temple XI, the most important discovery being that of a long, well-preserved hieroglyphic inscription flanking one of the temple's principal doorways. Mr. Strömsvik also undertook further repair of the Hieroglyphic Stairway, replacing a

number of carved blocks of which the exact former position is unknown but which, lying scattered at the foot of the stairway, were exposed to serious damage. These stones are being set in such a way that future students cannot confuse them with the steps actually found in place. In their present location they not only are safe from harm, but serve to restore to the stairway much of its original grandeur.

Miss Tatiana Proskouriakoff spent several weeks at Copán gathering materials for a series of drawings which will convey much more clearly and graphically than can be accomplished by any other method the probable appearance of the various buildings as they existed during the city's occupancy.

J. M. Longyear devoted a second field season to study of the pottery of Copán. In 1938 he had identified the major local types and had determined the succession of the principal ceramic periods. The present year, additional test pitting and trenching netted some 20,000 more pottery sherds. Among them are many of sufficient size to give better information than had previously been available regarding the shapes of vessels and their decoration. They also include a number of pieces of nonlocal manufacture which throw light upon chronological relations and trade contacts between Copán and other cultural centers both within and without the Maya area. Miss Shepard was at Copán in April to gain firsthand information as to archaeological and geological conditions in the valley, and to make preliminary technological observations on the pottery.

During the season the Government of Honduras constructed at the modern town of Copán a museum to house the pottery and other small specimens found in the excavations, and such finer pieces of sculpture as require protection from the weather. The museum building, erected under Mr. Strömsvik's supervision, contains exhibition halls, library, laboratory, and storage rooms.

31.7.

GUSTAV STRÖMSVIK

Copán

YB 39:264–265, 1940

The work of excavation and repair at the ruins of Copán, Honduras, which has been in progress since

1936 in cooperation with the Government of Honduras, was continued during the past winter. Mr. Strömsvik was assisted by Mr. Frank Lee. The two major activities of the season were completion of the resetting of the great Hieroglyphic Stairway and further investigations of the ballcourt and the temples adjoining it.

The Hieroglyphic Stairway, perhaps the most imposing single element ever achieved by Maya architects, rose between wide sculptured balustrades to a temple crowning a lofty pyramid. From bottom to top, carved upon the risers of its 62 steps, ran a calendrical inscription, the longest so far discovered in the Maya area. When the work of repair was started, the lowermost 15 steps were still in their original position; 15 others that had slid-downward en bloc almost certainly came from a space beginning 12 steps above. The blocks of stone which had composed the rest lay about the court in front of the stairway, where they had been carried during the course of earlier excavations at Copán.

With the assistance of Dr. Morley, the order of the blocks was worked out as fully as possible, and they have now been replaced in the stairway. This was done not only to restore the stairway to its former magnificence, but also to preserve the inscribed stones from the vandalism and natural deterioration to which they were exposed in the court. Some of the steps are incomplete; a few possess only one or two of their original stones, the others having been either crushed beyond recognition or carried away. But all rebuilt sections are now so marked that the student can distinguish between those elements which surely occupy their correct positions, those which are probably rightly placed and those as to which doubt exists. They are also set in such a way that the order of the individual stones can easily be changed in the event that further research indicates errors in the present arrangement.

The stairway was decorated with a central ascending line of human figures, five seated and one reclining. The first seated figure was found in place at the tenth step; many years ago the second, which was at the twentieth step, was, with permission of the Honduran government, taken to the Peabody Museum of Harvard University; the third lying in fragments in the court, has been restored on the thirtieth step; and the reclining figure rests on the thirty-seventh. The fourth seated figure is restored on the forty-fourth, the uppermost on the fifty-fourth. A smaller standing figure has been placed in the center of the short unsculptured stairway which continued upward from the pyramid's summit platform to the top of the substructure supporting the temple. The latter had long ago collapsed, and the elaborately sculptured stones which ornamented it were found scattered on the

flanks of the mound. Its hard lime floor, though much broken by falling rocks and torn apart by tree roots, still remained. The pieces were fitted together and cemented in place to indicate the size in shape of the temple's single chamber.

The stones composing the balustrades of the main stairway, having been relatively small, were badly crushed in the general ruin of the structure; many of them, too, seem to have been carried away for building purposes during the years before the government put a stop to that practice. Such as remained we assembled and reset. "Owl elements," wing-like stones on each of which was carved a conventional owl's head in front view, occurred at intervals of five steps. Being broader than the balustrade, they protruded from its sides.

Excavation, study, and repair of the ballcourt were continued. It had been determined, during former seasons, that the existing court had been the latest of three such structures which had successively occupied approximately the same position. During 1940, the plans of the two earlier courts were worked out from such parts of them as had remained buried below the latest one. Of the two temples which had flanked each of them, very little was left. It was determined that the first court had been built on virgin earth and connected with earlier structures to the east and south. The second was built on exactly the same plan as the first, but the floor level was raised about 60 cm. The latest court was raised about 20 cm above the second and was situated about 6 m to the north and 2-5 m to the west, the north end having been swung some 4 degrees west of the axis of the earlier courts which was about 2 degrees east of true north. This change was apparently made when the latest increment of the pyramid of the Hieroglyphic Stairway was added. All three courts are of the same size, with benches of the same height, width, and pitch of slope. Only the latest court was paved with stone. Hieroglyphic inscriptions and sculpture were found only with the two latest courts. The paving of the playing surface of the third court, which had been much disarranged by tree roots, was relaid in 1938; during the past season both benches were repaired and four large stone parrot heads that had fallen from the benches were replaced, thus completing all 6, three on a side. The low vertical walls back of the sloping benches were rebuilt, and the substructures of both flanking temples were reconditioned. The outer walls of the temples were relaid up to the spring of the vault. At two places the stepped vaults of these temples are still in position to within a couple of courses of the capstones, but these must be consolidated before long, to prevent collapse and loss of this important evidence of vault construction.

Minor activities during the past season included the repair and re-erection of stelae and Altar 13, the

raising and blocking-up of Altar 14, and the re-erection of the uncarved stelae of this altar. For its better preservation, Stela 6 was also repaired and re-erected. The perplexing problem of how the Court of the Hieroglyphic Stairway was drained was solved: a drain 65 cm deep and 70 cm wide was found entering under the west end of Mound 11, starting about 20 m west of Stela N and running southward under the Acropolis; the outlet could not be found. A small tomb with a badly decayed skeleton was found in the north end of Mound 7; two of the accompanying vessels may be of southern origin, and the third is of Plumbate Ware, which may indicate that the burial dates from after the close of the Old Empire. The most striking single find of the season was the gigantic and well preserved human head, carved in stone, at the northeast corner of Temple II. It is 85 cm high and is part of an enormous human figure which adorned the northeast corner of the temple; the hands and feet had been found years ago. There is another much broken head which belonged to a similar figure at the temple's northwest corner.

Mr. Shook spent six weeks at Copán, making a detailed study and section of the north half of the river-cut face of the Acropolis, with minor excavations to determine the lowest building levels. He also excavated a glyphic panel at the east end of Temple II. This is the eighth panel of this type found in that temple, but the only one with its complete text in good preservation. During his stay, Mr. Shook added to the master map of the Main Group all data which had accrued since 1937.

31.8.

GUSTAV STRÖMSVIK

Copán Project

YB 45:201–203, 1946

The 1946 activities of the Copán Project were as follows: repair of the earthquake damaged monuments at the ruins of Quiriguá; study of the cause of the deterioration of the monuments at Quiriguá and Copán; continued digging at Copán for recovery of ceramic material; re-erection and repair of the remaining four stelae in the valley of Copán; mapping and reconnaissance digging for ceramic material at the supposed site of Chaves' conquest of the Maya under Copán Calé.

On January 15 repair work started at Quiriguá, on Stelae E and J, damaged by the severe earthquake of August 1945, which caused much destruction in the neighborhood. Both E and J had been erected and repaired by the Carnegie Institution in 1934. The violence of the shake having caused considerable chipping around the lines of the old fractures, it was necessary to replace these chips and strengthen the shafts against further damage.

In the case of Stela E, previously broken across the neck of the figure, two steel dowel pins, placed in 1934, had held the top from being thrown off, but had not prevented a slight rocking action that dislodged a number of fairly large flakes on both sides above and below the line of fracture. To prevent a similar occurrence in the future, a 2.5 inch [6.4 cm] hole was drilled lengthwise through the center of the shaft, three 0.75 inch [1.9 cm] reinforcement steel rods, 25 feet [7.6 m] long, were threaded down through this, and the remaining space was filled with a mixture of half sand and half ordinary cement. Afterward the flakes that had been thrown off were replaced and held with iron pegs set in holes drilled through the fragments and into the monument. Such cracks as were left were filled with cement and drilling dust of the same rock, a mixture approximating the natural color of the stone.

Stela J, originally broken across the feet of the figure and badly chipped around the break, was repaired in 1934. At that time a steel rod was placed in a hole longitudinally drilled from top to bottom. This had held the shaft upright, but did not prevent some rocking and more chipping during the recent shake. This season it was reinforced by sinking four clamps, spanning the crack, into the four sides of the stela. The clamps were of 1 inch [2.5 cm] steel, over 1 m long, with points 15–20 cm long drilled into the face of the monument. The chips were replaced in the same manner as on Stela E, and the rods were covered with a similar cement-dust mixture. The present repair should make Stela J at least as strong as it was originally.

During delays in the work on the stelae, Zoomorphs M and N were cleaned, repaired, and set on low pedestals. Materials and labor, as well as quarters and board for Mr. Strömsvik, were supplied by the United Fruit Company.

During the more than a decade in which the monuments at Quiriguá and Copán have now been under close observation, considerable deterioration has taken place. This is caused by mosses and lichens whose tiny roots penetrate between the particles of the stone and loosen them, apparently by both mechanical and acid action. It is imperative for the future preservation of the monuments to remove these growths and prevent their re-establishing themselves, and to find a hardening agent for the softened surfaces. Obviously

the Maya faced the same problem, both at Copán and at Quiriguá; their practice, however, of coating monuments with lime plaster and in some cases with red paint must have served to prevent the damage now caused by this type of vegetation.

To fill gaps in existing knowledge of ceramic sequences at Copán, several exploratory trenches were opened south of the Acropolis, after February 10. These were continued and enlarged by Dr. Longyear after his arrival at Copán March 22.

A resident of Copán, digging for adobe in a small mound at the southern edge of the village, found eight fine large jade plaques, each carved on one side with serpent motifs, and a human figure in the classic Copán attitude with hands on breast. At the main ruin there came to light an interesting early drain running toward the river from a long-buried court in the present flying field. This was followed for about 200 m. It was found to have been built in several sections, but had become closed and forgotten during the later centuries of the city's existence.

On recommendation of Dr. Morley, the four remaining fairly complete unrepaired stelae in the Copán valley were re-erected and repaired as far as possible. These are: Stela 10, the West Piedra Pintada; Stela 13, the East Piedra Pintada; Stela 15, lacking its lower third, from Copán village, set up in the museum yard; and Stela 19, in the small valley west of Hacienda Grande, set up in its original position.

Study, cataloguing, and repair were carried out in the Copán Museum, but much more remains to be done.

At the invitation of Mrs. Doris Zemurray Stone, the valley of the Comayagua River was visited during the last week of February. The many Comayagua sites, representing a long period of occupation, merit closer investigation. A very interesting burial cave, newly discovered, was also partly explored. An archaeological museum has been opened in the town of Comayagua; it contains important specimens the study of which will throw much light on the complex problems of Copán and neighboring sites.

The site, mentioned by Fuentes y Guzman in his *Recordación florida*, where Chaves found and fought Copán Cael in the sixteenth century was visited in order to obtain pottery dating from the early historic period. Sr. Jesus Núñez, the representative of the government of Honduras at Copán, and Mr. Strömsvik left Copán by air April 22 for Nueva Jocotepeque. Riding up the broad Lempa valley, past the village of Vado Hondo, the party arrived at the village of Santa Anita; here they were shown a fine polychrome "Copador" vase that had been found with a burial in the river bank about 1 km above the village, where there is a group of rubble mounds on an alluvial plain. In the

riverbank were seen sherds of Copador, bichrome, and monochrome pottery, and fragments of round-bottomed metates and two-faced manos. About four hours' ride up the valley, past Santa Fe, brings one to the settlement of Piñuelas, the last before crossing badlands to the site now called El Rincon del Jicaque, which is supposed to be the site defended by Copán Cael. It is on a mesa in the Comayagua valley, a peninsula almost encircled by the Lempa River, which there flows in a canyon 80–100 m deep. The narrow neck is closed by a rough stone wall, 2–3 m high, and could be very easily defended. On the east side an intricate system of toe holds gave access to the river; these were probably used only during sieges. Over 50 house mounds were noted, but excavation would no doubt reveal many more. Only one mound had pyramidal form, about 3 m high, probably the substructure of a small temple or shrine. The house mounds were rectangles bordered by a base course of rough stones, with tamped gravel and ash floors raised about 20–30 cm above ground level. The small amount of rubble on the floors suggests that walls were of wattle and daub and roofs of thatch. Fragments of unshaped slab metates and short two-faced manos were found. Considerable digging in the scant topsoil yielded very few potsherds, mostly from crudely made water jars. It is obvious that the site was but briefly occupied.

31.9.

JOHN M. LONGYEAR
Copán Pottery

YB 45:203–205, 1946

Dr. Longyear spent six weeks at Copán in March and April 1946, gathering ceramic data to supplement the material collected in previous years [Chapters 31.5 and 31.6] and observing the results of excavations conducted at Copán during the last few seasons. Six stratigraphic trenches were dug for pottery specimens, a large portion of the latter being brought to the United States for study. In addition, all vessels excavated since 1939 were photographed and described, and the catalogue of the museum at Copán was brought up to date. At the conclusion of his stay in Copán, Dr. Longyear paid a short visit to San Salvador, to inspect the pottery excavated at Tazumal in 1943–44 by Mr. Stanley H. Boggs.

A rich burial area, some 200 m south of the Acropolis, was selected as the site of the principal stratigraphic trench dug at Copán this season. Excavations had been made here in 1942 by Mr. Strömsvik [Chapter 30.2], and deep sherd-bearing deposits found. The new trench, 18 m long, was excavated in blocks 1 m sq taken down in arbitrary levels 50 cm in thickness. The other five trenches, to the west and south of the Acropolis, yielded specimens supplementing those recovered from the principal trench.

From field observations the following tentative conclusions may be drawn: The lowest stratum in the trenches consisted of a dense deposit of monochrome and bichrome sherds, intermixed with large quantities of fresh-water snail shells, together with a few handmade figurines of Playa de los Muertos type. Overlying this earliest level, the first polychrome pottery appeared strongly characterized by basal flanged bowls of Petén Tzakol type. In the uppermost, or latest, strata, the polychrome changed to local styles, with occasional specimens of Ulúa-Yojoa wares. In the main, this sequence had been worked out in 1938 and 1939, but two of this year's discoveries were of outstanding importance: the association of handmade figurines with the earliest Copán pottery, and the great preponderance of basal-flanged bowls in the early polychrome levels.

Burials found this year conformed to the sequence established by Strömsvik in 1942 [Chapter 30.2]; that is, early interments were extended, with monochrome and bichrome pottery offerings, whereas later skeletons, with inlaid teeth, were buried in flexed position, and offerings, where present, included polychrome wares. In addition, two crude secondary burials were uncovered in a rubbish deposit just west of the Acropolis. It is possible that these are associated with the post-Acropolis occupation of Copán.

Shortly before the end of the season, a level representing an early land surface was discovered in an old river cut south of the Acropolis. This level lay below a stratum containing the earliest pottery yet found at the site, and was separated from it by 40 cm of sterile river clay. About 5 sq m of the deposit was uncovered and carefully excavated before the end of the season. Averaging 10 cm in thickness, it consisted almost entirely of charcoal, flint and obsidian chips, and broken animal bones. Not a single potsherd or other evidence of ceramic industry was recovered. The charcoal appeared to be scattered rather evenly through the deposit, and thus may have resulted from some natural cause, such as a forest fire. Later in the season, however, Messrs. Kidder and Strömsvik excavated further

and located some fire-blackened stones, possibly the remnants of a hearth. The most interesting feature of this early level is the flint and obsidian collection, which consists entirely of irregular flakes, no prismatic cores or parallel-sided blades, so common in the pottery levels above, having been found. None of the flakes have been worked into definite tools, but most of them bear secondary use-chipping, along one or more edges. In fact, it is possible to distinguish whole groups of rude implements, such as scrapers and points, by the characteristics of these reworked edges. In an area of flood-plain river deposition, we cannot claim great antiquity for this, level solely on the basis of the 40 cm stratum of sterile clay separating it from the pottery-bearing strata above. It is almost impossible to believe, however, that any deposit contemporaneous with the ceramic industry at Copán could accumulate without the presence of a single potsherd or obsidian blade. At present, therefore, this level must be assigned to a pre-pottery stage, and be considered to represent the most primitive culture yet found in this part of Central America.

Dr. Longyear has also been engaged in study of the design motifs of Copán polychrome pottery. His analysis, although still in an early stage, shows that the local painted wares were rigidly stylized, both in decorative motifs and in the shapes of the vessels on which given motifs could be placed. It is now possible to isolate these Copán styles from those of imported wares, and also to identify them whenever they occur in the ceramic context of other sites. The importance of this study was fully realized when the pottery from Tazumal, El Salvador, was examined. Many of the polychrome wares of the latter site resemble Copán vessels so strongly that there can be no doubt they both stemmed from the same artistic tradition. In other respects, however, the two ruins are entirely different. Here, then, is another example of the duality of Maya culture, first emphasized by Thompson. The basic or lay trait of pottery manufacture and design bridges over the more obvious dissimilarities between Copán and Tazumal dissimilarities caused by Copán's falling under the influence of the classic Maya hierarchic cult, while Tazumal remained unaffected by it. Further studies of this sort will not only greatly enlarge our knowledge of ancient Mesoamerican cultural origins and relations, but will also help divert the field archaeologist from the straight and narrow path of stratigraphic sequences and statistical potsherd analyses, a path from which it would do many archaeologists no harm occasionally to stray.

32.0. NICARAGUA

32.1.

FRANCIS B. RICHARDSON

Nicaragua

YB 40:300–302, 1941

As was stated in the introduction to this report, Mr. Richardson, who went to Nicaragua to study relatively recent stone sculpture, was diverted from that end by the necessity of investigating a series of ancient human footprints found in deeply buried volcanic deposits near Managua.

A similar discovery had been made in the seventies by Earl Flint, who was working for the Peabody Museum of Harvard University. Flint's attribution of great age to the footprints was received with considerable skepticism, no attempt was made to follow up the discovery, and the whole occurrence was soon practically forgotten. Mr. Richardson, however, who had read Flint's reports and his correspondence filed at the Peabody Museum, felt that the matter should be investigated further. On arrival at Managua, he accordingly made inquiries and learned that footprints were still from time to time encountered in a quarry in El Cauce, a short distance west of the city. He, at once visited the site, where by great good fortune the workmen were just bringing some of the tracks to light.

Extensive excavations, carried out with the cordial support of President Somoza, revealed most interesting conditions, best summarized by quoting the preliminary report of Dr. Howel Williams, of the University of California, who, on being appealed to by the Division, generously sacrificed his Easter vacation to fly to Nicaragua and examine the deposits.

Before the footprints were made, there had probably been millions of years of volcanic activity, as they are underlain by hundreds of feet of ash. It may be, however, that about the time the prints were formed the craters, a short distance south of Managua, burst into unusually violent eruption. I hope that microscopic study of the deposits will throw light on this point.

Just before the prints were produced, volcanic "mud flows" (technically known as lahars) swept across the plains around Managua and emptied into the lake. It may be that these were formed by temporary damming of the rivers that drain from the highlands to the

south, at a time when the cones and craters of Asososca, Nejapa, Tiscapa, etc. were particularly active. Whatever the cause of the lahars, and other possible causes are easy to imagine, they inundated a wide area. Soon after they came to rest, the prints were impressed. I say "soon" because the deposits left by lahars tend to harden rapidly. Somewhat similar deposits were laid down on the slopes of Lassen Peak in California in 1915 and within a few hours it was difficult to stamp an impression on them with the feet. Lahars which sweep down from the volcano of Java are known to behave in the same way. Incidentally, the laharc deposits of Managua are remarkably like those which buried Herculaneum in AD 79.

Shortly after the making of the prints possibly even while they were being made they were covered by a thin veneer of black cinders. Then followed another lahar, another eruption of black cinders, and then a rapid succession of thick lahars. These last are now represented by the thick stratum quarried and used as a building stone in Managua.

An interval of quiescence ensued. In the region of El Cauce, rivers excavated a channel some 20 m wide and at least 3 m deep. They cut not only through the layers of volcanic mud but far into the underlying ashes. Slowly the channel was filled with sand and gravel. Subsequently, a distant volcano, perhaps in the vicinity of Masaya, erupted showers of white pumice. About El Cauce the pumice accumulated to a depth of approximately 50 cm. Once more quiet followed. Rivers cut new channels through the pumice; elsewhere a soil up to 1 m thick was developed. Renewed eruptions covered the soil with ash; another soil, up to 30 cm thick, was formed; more ash fell, and finally the topmost layer of soil on the present surface was laid down to a depth of 1.25 to 1.5 m. The record of events since the prints were impressed is thus a long one, as four layers of soil were formed and a deep river channel was cut.

The tracks were made by a number of barefooted adults. All those uncovered by Mr. Richardson were going in the direction of a point which at present protrudes into the lake some 500 m to the northwest (others, however, are reported by quarrymen to be differently oriented). First to pass over the area examined were four or five individuals, who sank ankle deep into the then fresh and very soft mud. Somewhat later others passed. The deposit had by that time become much firmer, but its surface was still sufficiently plastic to receive absolutely perfect impressions. These indicated that the people had been walking rather than running; the steps are so short as to suggest that they may have been carrying heavy burdens.

One is, of course, tempted to infer that the makers of these tracks were fleeing from an eruption. Tracks of deer, otter, a large bird, and a lizard made at approximately the same time, and on what must then have been a bare open plain, hint at a disregard of danger that might be taken as evidence of panic. Since, however, only a few square meters of this intriguing record have so far been exposed, it is unsafe to speculate too freely.

The problem of greatest importance is, of course, that of the age of the footprints. That they are of respectable antiquity is beyond doubt, but in the absence of contemporary artifacts we have no archaeological evidence bearing on this point. In the surface humus laid down after all volcanic activity had ceased there are, however, many potsherds, and some of these appear to represent a relatively early culture. If so, and if one allows time for deposition of the intercalated humus strata and the cutting of the now buried stream bed through the thick layers of hard rock overlying the footprints, the latter may indeed be extremely old.

During the coming season the trail will be followed as much farther as means will permit. Although it is perhaps too much to hope that remains of people themselves will come to light, it is possible that artifacts may be found, and probable that further evidence will be obtained as to conditions obtaining at the time the footprints were made. Careful search will also be made in the humus immediately below, for that of course represents the surface on which the people must have lived prior to the outpourings of mud. The alluvial material in the stream bed will be examined, as well as the beds of humus laid during periods of quiescence. Stratigraphic studies will be carried on in the latest humus. Relatively large amounts of this can be sectioned, as its excavation will not entail quarrying off the great overburden that masks the deeper deposits. Finally, every attempt should be made to ascertain the approximate age of the flows by volcanological research and the use of such chemical and spectroscopic techniques as can be brought to bear on the problem.

It is to be hoped that the site of these remarkably interesting and possibly very important evidences of prehistoric man may be acquired by the Government of Nicaragua, and the footprints exposed this year and next be preserved *in situ* as a national monument.

President Somoza has already aided the work of conservation by the building a diversion dam and the opening of a large drainage ditch, which will turn flood water away from present and future excavations.

32.2.

FRANCIS B. RICHARDSON

AND KARL RUPPERT

Nicaragua

YB 41:269–271, 1942

As was recorded in the last annual report, tracks of barefooted human beings and of various animals and birds are from time to time found during quarrying operations in a deeply buried volcanic stratum at El Cauce in the vicinity of Managua. In 1941 Mr. F. B. Richardson investigated a recently discovered set of these footprints. The layer in which they occur was the product of an eruption from some vent on higher land. From it a sheet of semiliquid mud flowed down toward Lake Managua, and while this was in process of hardening, but still plastic enough to receive perfect impressions, the people and animals passed across it. Almost immediately thereafter a fall of dry cinders covered and preserved the tracks. Subsequently the area was blanketed by other mudflows, now, like the footprint stratum, hardened to stone. Later the entire series of layers was cut through by a small stream whose bed, in course of time, became filled with silt and water-rolled boulders. Still later there was a heavy fall of pumice, followed by an interval of quiescence with further stream erosion, deposition of humus, more pumice falls, and, finally, a cessation of volcanic activity and the deposition of the present topsoil to a depth of 1.25–1.5 m.

That a long time must have elapsed since the making of the footprints is certain; but until the volcanological studies of Dr. Howel Williams, of the University of California, who is cooperating with Mr. Richardson in this investigation, can be carried farther, no estimate of the period involved is possible. In the meantime, however, Mr. Richardson has continued work at the site, and Mr. Karl Ruppert devoted the past season to study of the archaeological remains found in the recent surface deposits.

The area of the original discovery was widened and the tracks were followed for a distance of some 20 m. A careful count showed that 17 persons had passed, going in a straight line toward a low promontory that juts into the lake. The tracks originally identified as those of deer have since been shown to have been made by a large peccary.

Another discovery of animal prints, made during the past season, promises to be of great interest, both archaeologically and paleontologically. At a stone quarry on higher land some distance away there has

been exposed a sequence of mudflows, apparently from the same source as those of El Cauce. The lowest of these, which may well represent the identical flow seen at the base of the El Cauce series, was found by Mr. Richardson to contain tracks of a large cloven-hoofed creature. Latex casts were submitted to Dr. Thomas Barbour, of the Museum of Comparative Zoology at Harvard University, and to Dr. Paul O. McGrew, of the Field Museum in Chicago, both of whom identified the prints as those of bison, an animal which never seems before to have been reported from Central America.

If man and bison, an animal certainly long extinct in the region, are found to have been contemporaneous, we shall have evidence of the high antiquity of the El Cauce footprints, which may indeed be the oldest traces of human occupancy yet found in Middle America. It is therefore outstandingly desirable to gain even the smallest scrap of knowledge as to the culture of these people. The prospects of such a discovery are however, remote, as the surface on which they lived now lies buried under several meters of solid rock, pumice, and earth and is accessible only in the few relatively tiny spots where quarrying operations have removed, the overburden. The vicinity of the footprints is not promising, as the pre-mudflow land thereabouts was a gentle slope, apparently an open and perhaps barren plain. As such it would have been ill suited for a dwelling place, and the chances of finding artifacts on, it are very slight. But since the government drainage ditch made it possible to reach part of the old surface at one side of the footprint area, it, seemed worth to expose and search as much of it as was reachable. Some 60 m of footprint stratum were, accordingly removed and the top 30 cm of the underlying deposit passed through a fine-meshed, screen. Nothing, unfortunately, came to light.

Through the good offices of President Somoza, the site has been acquired by the Government of Nicaragua and a resident custodian has been appointed. Over the tracks Mr. Richardson has erected a permanent building, whose tiled roof protects them from the weather while its open sides permit their examination at close hand.

Although determination of the age of the footprints is primarily a volcanological problem, a minimum date, archaeologically speaking, can be arrived at through study of the cultural remains in the superficial deposits, for the oldest of these must be much younger than what lies under the great accumulation below. Mr. Ruppert therefore devoted the season to surface excavations at El Cauce and elsewhere in the neighborhood of Managua.

The pottery-bearing level of brown soil at El Cauce is 3 m above the footprint stratum, varies in thickness

from 1.3 m to 1.6 m, and, according to Dr. Williams, "while apparently of aeolian origin, much must have been laid down by running water." A number of pits and trenches were dug and yielded abundant sherd material apparently of a single not very remote period.

During the previous season a burial ground had been discovered east of El Cauce and south of the railroad tracks. In some of the boot-shaped jars were fragments of human bones. The area was re-examined during the current, season. Although a number of caches of vessels were uncovered, none contained skeletal material.

A high point of land northwest of El Cauce protruding slightly into the lake seemed a likely place for a series of trenches. The yield of sherds was extremely small. In general the wares are similar to those from El Cauce. The number of sherds worked as net-sinkers was relatively large. Sherds obtained from trenches at Las Mercedes Airport, 9 km east of Managua, were again of wares similar to those from El Cauce.

At the close of the season a mound to the east of El Cauce, on the property of Don Salvador Salgado, was examined. A pit in the top of the mound is said to have,

been made by pothunters. A trench on the north side extending from the valley floor inward to the center disclosed a rough stone-faced platform 50 cm high and 6 m wide. The mound, 3.5 m high by 10 m in diameter, resting on this platform was faced with unworked stones. Near the center and 2 m above its base was a cache of three vessels. The sherds, varying little from those at El Cauce, did however include several pieces of Usulután pottery, a ware which, in Guatemala and El Salvador, is found only in the earliest ceramic horizon. The presence of Usulután fragments, probably dating from a period long anterior to the erection of the mound and owing their presence there to accidental inclusion in its fill, argues for a relatively ancient occupancy of the Managua Valley subsequent to the latest volcanic activity.

Analysis and interpretation of the ceramic material have not yet been made. A wide trade in pottery vessels is, however, attested by the presence of sherds of Honduranian (Ulúa Valley and Lake Yojoa) and Salvador wares. Over 75,000 sherds were examined and sorted, and a representative collection will be brought to the United States for final study.

33.0. QUINTANA ROO

33.1.

GUSTAV STRÖMSVIK, H.E.D.
POLLOCK, AND HEINRICH BERLIN
Exploration in Quintana Roo

YB 53:289–292. 1954

The explorations described below were carried on by Strömsvik and Pollock between February 23 and 28, and by Berlin and Strömsvik between May 24 and 29, 1954. Previously, one of our workmen from the village of Telchaquillo, Yucatán, had been sent into the area to gather information on the location of ruins and to report on roads and living conditions. His report assured us that we could make the trip by truck and that we could obtain some food supplies and camp facilities at the village of Ichmul, the site of certain ruins we wished to observe.

The first trip started from Telchaquillo, going by way of Tekit, Teabo, Ticul, and thence to Peto over the newly built highway from Mérida to the last-named town. The second trip left from Mérida, using the highway to Peto. Beyond Peto, and the end of road normally considered passable by automobile, our course was generally east through the village of Progreso (12 km from Peto), Dzonotchel (24 km), and Calotmul (31 km) to Ichmul (43 km). This is the old road from Peto to Santa Cruz de Bravo, now known as Carrillo Puerto.

Immediately east of Calotmul, we stopped to observe a small ruin site of four mounds. Two of the mounds are each about 8 m in height, one being a pyramidal structure, the other probably having been a two- or three-storied palace-type building. On both structures Puuc-type stones are lying about, and part of a vault of very crude masonry is visible near the bottom of the second. The vault cannot be placed as to type in this relatively unknown area. Possibly it is to be associated with the crude vaulting, seemingly of late period, seen subsequently at Okop. The remaining two mounds at Calotmul were smaller and without notable features showing.

Ichmul, which lies just over the border in Quintana Roo, is an old settlement, as is shown by Ciudad Real's mention of the town in the sixteenth century. At present it is more notable for its colonial than for its aboriginal ruins. Overgrown streets and tumbled-down remains of colonial buildings extend a kilometer or more in all directions from a large central plaza. Two imposing churches, the second and bigger one never completed,

a cuartel, and an unfinished cabildo face on the plaza. The more important aboriginal remains, consisting of three large pyramidal mounds and the ruins of an enclosed quadrangle, all rising from a large terraced platform, lie just south of the plaza. Other terraces, courts, and smaller mounds lie farther south, and another group of ruins was observed east of the plaza of the town. On each of the principal pyramids are elaborate fortifications in the form of head-high walls of stone, clearly of colonial or later origin. Tradition in the settlement, which consists of a schoolmaster and possibly a dozen families that seem only recently to have taken up residence in the abandoned town, is that the fortifications were built at the time of the War of the Castes. The eighteenth century date of the unfinished church, however, suggests that the place was abandoned at an earlier time.

As might be expected in a town of the size that Ichmul once was, the ancient Maya structures are in a shocking state of ruin. They were undoubtedly used as quarries to build the impressive colonial structures, and the fortifications on each pyramid have leveled the remains of any buildings that may have stood there. In the eastern and largest of the pyramids about halfway up the mound, we observed and explored a system of vaulted passages that ran into the center of the structure. These were of crude construction, built entirely of roughly shaped but otherwise unworked stone. Toward the western edge of the ruins, just south of the colonial cuartel, the section of a partly fallen vault protruded from the side of a large platform. This was of interest in showing a sequence of different kinds of masonry. The primary vault, which was of Puuc-type construction, was built against, and was clearly later than, a battered wall, apparently the old face of a terrace, of well cut and dressed veneer masonry. This wall might be of Puuc Period or earlier. Inside the vault, and secondary to it, was a smaller vault of crude masonry comparable to that seen in the eastern pyramid. This sequence suggests that the crude style of masonry is later than typical Puuc construction, but we should not put much weight on this single example.

We obtained a small, and hardly adequate sample of pottery from a single trench and from digging around the western vault in Ichmul. The sherds were mostly of colonial and Puuc types. There as a sprinkling of sherds similar to, southern Classic types. Owing to the difficulty of distinguishing Mayapán Red Ware from colonial pottery, in the absence of distinctive rim forms, one cannot be certain that Mayapán Period ceramics are not represented at Ichmul. Only further excavation can answer this question. On the basis of pottery findings and of architecture, one guesses the major period of the site to be Puuc, or Late Classic.

About 4 km south of Ichmul is the abandoned colonial settlement of Querul or Xkerul, a name one suspects to be a Spanish corruption of a Maya word. Halfway along the trail to this site we noted an ancient road, or *sacbé*, which we followed to its termination at a pyramidal mound north of the ruins of a colonial church. The mound, which stood about 9 m high, was a tumbled mass of fallen stone with no standing masonry showing. It was the only ancient structure, with the exception of the *sacbé*, seen at Querul. The *sacbé* is 10–12 m wide and at places stands at least 2 m high. We did not trace the road to its terminus at Ichmul, but there is little doubt that it runs to that site. There is no reason to think that the pyramid at Querul and the *sacbé* are not of the same period as the ruins of Ichmul.

Strömsvik and Pollock made a trip of a single day to the ruins of Okop, or La Aguada, as the site is locally known, and the subsequent journey of Berlin and Strömsvik was devoted entirely to that site. The ruins lie southeast of Ichmul on the road to Santa Cruz de Bravo. The only sizable settlement passed was Sabán, an old colonial town that appears also to have been abandoned and reoccupied, 23 km from Ichmul. Eleven kilometers farther along one passes a tiny cluster of huts that preserves the name Okop, and 2 km beyond is the small freshwater lake that gives the name La Aguada to the ruins. There is a group of a dozen mounds 100–200 m west of the lake and another group about 1 km north. The two are connected by a *sacbé* 12 m wide.

During the few hours spent by Strömsvik and Pollock at the site, only the northern group was examined, although the existence of the southern was noted. The group consists of three good-sized pyramids, ranging from about 9 m to 15 m in height, and several smaller mounds that rest on a large platform some 150 m north and south, and that much or more in an east-west direction. The pyramids are arranged about a plaza on this elevation. To the east of the pyramids are more mounds, but we did not explore that area. South of the great platform is a small pyramidal mound on the east edge of what seems to have been another plaza or court. In this second plaza, Strömsvik discovered a sculptured stela, half-buried and caught in the roots of a huge breadnut tree. In attempting to extract the stone, we broke our only axe, and it was not until the second trip to the site that the stela was finally brought to full view.

Two of the pyramids, the northern and eastern, support partially standing temple buildings at their summits. These are small, single-room structures built of crude masonry with rough vaults that step inward from the four sides of each room. The northern building has a single column in its doorway. Mixed with the crudely shaped stones of the walls are occasional

well cut stones of Puuc type. Over each entrance, in front of the lintel, is a sunken panel, a feature typical of late, East Coast architecture.

The stela, the only sculptured monument discovered at the site, shows a human figure carved in low relief with a short panel of hieroglyphs to the figure's right and a full-length panel to the left. The top of the stela, carrying the head and neck of the figure and the upper parts of the glyphic panels, is broken off and was not found. The glyphs are too eroded to be legible, but a fair amount of detail of the human figure remains. It shows a personage with toes pointed straight out at an angle of 180 degrees. Across his chest, from lower right to upper left, he clasps a Ceremonial Bar. On stylistic grounds, Proskouriakoff believes that the sculpture can be dated as early in the Late Classic Period, possibly around 9.9.0.0.0–9.11.0.0.0 in the Maya calendar.

As previously mentioned, the southern group lies about a kilometer distant from the ruins just described and is connected, to them by a *sacbé*. About 50 m short of the southern end of the ancient road, where it merges with a high terrace, is a round stone altar, 1.5 m in diameter, without carving. The principal structure of the group is a pyramid that rises some 20 m above the terrace and possibly 30 or more meters above natural ground level. The pyramid faces north; at the foot of the stairway is another circular altar, 2 m in diameter, also without carving. On top of the pyramid are the remains of a small single-room temple building. The strikingly heavy walls which enclose the tiny room are built of the same crude masonry seen in the temples of the northern group, and here again is seen at least one Puuc-type building stone among the otherwise undressed stones.

No other standing masonry was noted here. At least a dozen more mounds make up the group, the most notable being a large enclosed quadrangle just south of the pyramid.

No pottery that might assist in dating the ruins was recovered at Okop. The character of the remains, particularly the stelae, suggests that the major period of construction and of occupation of the site was Classic, probably Late Classic. The small temples on top of the pyramids seem to be of East Coast style and presumably are of later date.

33.2.

WILLIAM T. SANDERS

*Ceramic Stratigraphy of the
East Coast of Yucatán*

YB 53:292–293, 1954

Under a Carnegie Institution fellowship, Sanders began an archaeological reconnaissance of the East Coast of Yucatán. This survey was particularly directed toward learning the ceramic stratigraphy of that area and relating these findings to the better-known pottery of central and western Yucatán. Ever since the publication of Lothrop's monumental work on East Coast architecture it has been known that Toltec (Tula) influence in basic architectural forms, if not appearing in specific details, was general and widespread on the East Coast. The exact relation of this architectural style to that of the Toltec-Chichén and Mayapán Periods in central Yucatán is of great importance to an understanding of late period history in the northern Maya area. It was hoped that surface collecting of sherds and small-scale excavation at a number of East Coast sites might at least define more sharply, if not solve, those problems. The northern and northeastern coastal areas were selected as the beginning point for this ceramic survey. Most of the coast from Holbox on the north to Tulúm on the south was visited and worked. A number of sites in northern inland Quintana Roo were also tested.

One of the principal difficulties in doing work in this area is the lack of transportation facilities and of manpower for even small-scale excavation. It was decided to hire a small crew of workers from the Yucatán-Quintana Roo border town, of Kantunilkin for the entire field season. The quality of labor there is unusually high. The season was started at the often noted but never adequately described site which is of some size, situated in the village of Kantunilkin. It is an excellent jumping-off point for field work in northern Quintana Roo, there being two routes open to the coast. One is passable with jeep or truck and runs almost due north to village of Solfarino about 30 km away. From Solfarino there is a typical Yucatecan *tranvia*, or narrow-gauge rail line goes as far as Chiquila on the coast, opposite Holbox and at a distance of about 15 km. Along this route and the shores of Laguna de Yalahau six sites were visited and excavated.

The second route is a mule trail which goes from Kantunilkin to Leona Vicario (Santa Maria), about 30 km. From Leona Vicario there is another *tranvia*, about 40 km in length, which goes to the coast, terminating

at Puerto Morelos. Four inland sites were excavated along this tranvia.

Most of the remainder of the season was spent visiting and testing sites on the mainland, all within a kilometer of the beach, from El Meco, just opposite Isla Mujeres, in the north, to Tulum in the south. Three weeks were spent on Cozumel Island, an area rich in late-period sites. Fifteen sites were tested on the mainland, including such well known centers as Tulum, Tancah, Xelhá, Palmul, and El Meco. Approximately 11 sites were excavated on Cozumel Island. Most of these places were reached by boat; actually, more mileage was covered on foot, during the season as a whole, than by any other mode of travel.

At some sites adequate sherd samples were impossible to obtain because of the rocky terrain and the exceeding smallness of the site, in certain cases a single shrine situated on a rocky beach head. In at least 20 sites, however, good to fair sherd samples were obtained, although good building or occupation stratigraphy was rarely met.

Besides being tested for ceramic data, a high percentage of the sites were at least roughly mapped, and standing structures were photographed and drawn.

Extensive trail cutting was done in the vicinity of ceremonial centers to obtain data on house-mound types and their density. Also, information was collected on agricultural techniques and production by interrogation of workers from Kantunilkin, Leona Vicario, and Cozumel.

In general, the sites found or revisited are small and not very impressive in size, in quality of architecture, or in number of sculptured monuments. The largest seen was Tulum. The average site in the area is of one of two general types: 1. A single plaza ceremonial center surrounded by from three to five buildings, or 2. An isolated single-temple, or at times two-temple, beach shrine. The East Coast architectural style as defined by Lothrop seems to be a strictly coastal phenomenon, not seen at any of the inland sites visited.

Chronologically, the sites excavated run from Early Classic to the Conquest. This dating is based on architectural notes and a preliminary look at the pottery. Red Ware is abundant, and some of it looks like Mayapán Red. Censer Wares certainly related to Mayapán varieties are also common. Fine Orange is present at a few sites, but is exceedingly rare; no Plumbate was noted.

34.0. COBÁ

Coba is located around five small lakes. A series of elevated stone and plaster roads (sacbes) radiate from the central site to various smaller sites. Some of these causeways go east to the Caribbean coast, and the longest runs over 100 km to the west to the site of Yaxuná. The site contains several large temple pyramids, the tallest, known as Nohoch Mul, being 42 meters in height. Coba is estimated to have had at least 50,000 inhabitants at its peak of civilization, and the built up area extends over some 80 square km. The site was occupied by a sizable agricultural population by the first century. The bulk of Coba's major construction seems to have been made in the Middle and Late Classic periods, about 500 to 900, with most of the dated hieroglyphic inscriptions from the 600s. However Coba remained an important site in the Postclassic era and new temples were built and old ones kept in repair until at least the 1300s, and possibly as late as the arrival of the Spanish.

Knowledge of this expansive site was never completely lost, but it was not examined by scholars until the 1920s. John Lloyd Stephens mentioned hearing reports of the site in 1841, but it was so distant from any known modern road

or village that he decided the difficulty in trying to get there was too daunting. For much of the rest of the middle of the 1800s the site could not be visited by outsiders because of the Caste War of Yucatán. Maler visited Coba in 1893 and took at least one photograph, but unfortunately did not publish it and the site remained unknown to the archeological community. Thomas Gann was brought to the site by some local Maya hunters in 1926 and he later published the first description of the ruins later that year. Gann gave a short description to the archeologists of the CIW Chichén Itzá Project, which sent out an expedition under J. Eric S. Thompson. Thompson's initial report of a surprisingly large site with many inscriptions prompted Morley to mount a more thorough examination of the site. Thompson made a number of return visits to the site through 1932, in which year he published a detailed description. The site remained little visited due to its remoteness until the first modern road was opened up to Coba in the early 1970s. The Mexican Instituto Nacional de Antropología e Historia began archeological excavations in 1972 under the direction of Carlos Navarrete. At the beginning of the 1980s another

road to Coba was opened, regular bus service begun, Coba became a tourist destination with many visitors visiting the site on day trips from Cancun and the Riviera Maya. Only a small portion of the site has been cleared and restored.

34.1.

SYLVANUS G. MORLEY

The Four Cobá Expeditions

YB 25:274–277, 1926

The most important contribution of the year, indeed of the past five years in the field of Middle American archaeology, was the discovery, by the Institution’s Third Cobá Expedition, on May 24 of the site of Macanxoc, 50 mi. east and slightly south of Chichén Itzá. This site lies a mile and a half [2.4 km] southeast of the main group of Cobá, the existence of which has been known for 85 years, and is chiefly important because of the presence of eight sculptured monuments presenting eight Initial Series dates, practically trebling the number of Initial Series previously known in the entire peninsula of Yucatán, and promising to throw a flood of light on the early history of the country.

The ruins of Cobá were first noted by John Lloyd Stephens in 1841, although he did not visit the site personally.¹ Teobert Maler, the Austrian explorer, seems, however, to have been at Cobá, since a photograph of the so-called Castillo there taken by him is in the Museum of History and Archaeology at Mérida.

Dr. T. Gann and E. L. Crandall, the latter being the staff photographer of this First Expedition, visited the site on February 23 and 24, on behalf of the Institution, discovering two sculptured monuments (Stelae 11 and 12), both of which were so badly weathered, however, as to prevent the decipherment of their inscriptions.

Dr. A.V. Kidder and J.E.S. Thompson, G. Wiggin and R. A. Franks, Jr., the Second Expedition, were at Cobá and Nohoch Mul, an outlying suburb, March 16 to 18, and discovered two other sculptured monuments (Stelae 9 and 10) which also were so badly weathered as to prevent decipherment of their inscriptions.

Toward the end of May (22 to 28), Messrs. Thompson and Jean Charlot, the Third Expedition, visited Cobá, and on May 24 discovered the ceremonial center of the entire group, Macanxoc (meaning in Maya appropriately “it cannot be read”) with eight sculptured monuments (Stelae 1 to 8) presenting the eight Initial Series mentioned above.

During the week of June 4 to 11, Dr. Morley and Mr. Thompson, the Fourth Expedition, visited the site, and the final decipherments of the several dates were then made.

Of the eight monuments at Macanxoc, Stelae 7 and 8 are so badly weathered that beyond the bare fact that they formerly had had hieroglyphic inscriptions, no decipherment was possible. On the other hand, two of the remaining 6, Stelae 1 and 6, present two Initial Series each, a very unusual, though by no means unknown, feature in the *Corpus Inscriptionum Mayarum* (Morley 1948).

The following readings were made, those marked (?) though probably correct as given, are still subject to slight doubt (Table 34.1.1).

If the dedicatory dates (that is, the contemporaneous dates) of Stelae 6 and 1 are 9.9.10.0.0 and 9.12.0.0.0 respectively, following the usual Mayan practice where the latest date on a monument generally indicates the time of its erection, it will be seen that the monumental sequence at Macanxoc represents a series of lahuntun or 10-year period markers, a monument having been erected at the end of each 10-year period, or lahuntun, the city was occupied, according to a very ancient and practically universal Mayan practice (Morley 1920: 565–580).

It will be noted from the above table also, that one lahuntun ending, namely 9.9.10.0.0, was marked by the erection of two different monuments, Stelae 6 and 4, and that another, 9.11.0.0.0, has no corresponding monument at all.

It seems highly probable, however, in view of the fact that there are two other monuments at Macanxoc, Stelae 7 and 8, the inscriptions of which are too weathered to read, that one or the other of them originally recorded this missing lahuntun ending, thus making the sequence complete. Further, since both these monuments are certainly earlier than Stelae 5 and 1³ on stylistic grounds, it is not improbable that the other recorded the lahuntun ending 9.9.0.0.0, the next earliest in the sequence for which no corresponding monument has been found, making it the earliest monument at this group.

Table 34.1.1. Calendrical Decipherments, Stelae 1–5, Cobá.

Stela 6	9.9.0.0.0	3 Ahau	3 Zotz	354 AD
Stela 6	9.9.10.0.0	2 Ahau	13 Pop	364 AD
Stela 4	9.9.10.0.0	2 Ahau	13 Pop (?)	364 AD
Stela 3	9.10.10.0.0	1 Ahau	8 Kayab (?)	373 AD
Stela 2	9.10.10.0.0	13 Ahau	18 Kankin	383 AD
Stela 5	9.11.0.5.9	11 Ahau	18 Chen	403 AD
Stela 1	9.11.0.5.9	4 Muluc	17 Kayab	393 AD
Stela 1	9.12.0.0.0	10 Ahau	8 Yaxkin	413 AD

If Stelae 7 and 8 formerly recorded the lahuntun endings 9.9.0.0.0 and 9.11.0.0.0, as there are good grounds for believing, we will have a sequence of eight monuments marking seven consecutive 10-year periods, that is, from 9.9.0.0.0 to 9.12.0.0.0, presumably the length of time during which the city, where, they had been originally erected, was occupied.⁴

The style of architecture of the buildings and terraces at Macanxoc is so late, that there can be little doubt that these monuments were originally designed for some other location, and that they were re-used in late New Empire times, being erected where they now stand, perhaps as much as a thousand years after their original use in middle Old Empire times.

The two latest monuments, Stelae 5 and 1, present long series of time periods, at least 18 in the case of Stelae 6, and 19 in the case of Stela 1, every term of which has the same coefficient, that is, the number 13. It would seem as though originally 20 of these 13s had been recorded on each of these stelae, and in the case of Stela 1 the series terminates with 0 katuns, 0 tuns, 0 uinals, 0 kins, and the normal date 4 Ahau 8 Cumhu, the beginning point of Maya chronology, the two glyphs recording this latter date being separated by the corresponding Supplementary Series. The exact nature of these long numerical series is uncertain, but the repetition of the number 13 and the record of the normal date 4 Ahau 8 Cumhu suggest that they may have been priestly calculations dealing with the beginning of the Maya time count.

The real significance of Macanxoc, and its fundamental importance in the reconstruction of ancient Maya history lies in this group of eight contemporaneous stelae, which date from the early part of the Middle Period of the Old Empire, the latest date at Macanxoc, 9.12.0.0.0 on Stela 1, antedating the earliest date at Chichén Itzá, 10.2.10.0.0, on the lintel in the Temple of the Initial Series, by more than two centuries, thus pushing back the discovery of Yucatán a century earlier than the date given for that event in the Books of Chilam Balam.

The Macanxoc discoveries have enormously increased the authenticity and prestige of the Tulúm and Chetumal Bay Initial Series, 9.6.10.0.0 ([Chapters 1.4, 1.6, and 1.10]; Lothrop 1924) and 9.8.0.0.0 respectively, as representing contemporaneous dates. It may now be claimed with some reason that there is a continuous chain of dated sites running up the eastern coast of Yucatán linking the Old Empire region with the New Empire: La Honradez⁵ the northeasternmost Petén site now known), Chetumal Bay, Tulúm, Macanxoc and Chichén Itzá, the distances between any two successive links being not more than 125 miles [201 km] (Chetumal Bay to Tulúm) and in most cases much less.

In view of the new evidence afforded by the Macanxoc stela it now seems necessary to conclude that as early as the latter part of the Early Period of the Old Empire, perhaps a century and a half earlier than the date given for this event in the Books of Chilam Balam, Yucatán had been discovered via the East Coast route. The lacunae between the dated monuments from 9.6.10.0.0 (Stela 1 at Tulúm) down to the closing date at Macanxoc are less than 30 years in all cases. In fact the greatest chronological gap now comes between the closing date at Macanxoc and the earliest date at Chichén Itzá, less than 50 miles [80.5 km] apart in point of distance, but presenting a gap of more than two centuries in point of time.

The Macanxoc discoveries give strong color also to the very early tradition, reported by Padre Lizana that the original colonization of Yucatán was from the east; though greater numbers subsequently entered the peninsula from the west; and that in later times cenial (the Little Descent) had become synonymous with east and nohenial (the Great Descent) with west (Lizana 1633:4).

It seems not improbable that the region south, east and west of Cobá may yield other links in this chain of cities, which will still further shorten both the geographical and temporal gaps, until a continuous line of dated sites will have been found extending along the eastern edge of the peninsula intimately connecting the Old with the New Empire. For this reason the further investigation of the Cobá region is strongly recommended.

NOTES

1. The first notice of Cobá is given by J. L. Stephens in his *Incidents of Travel in Yucatán* (1843:2:340-341). In 1841 he was told of the site by the cura of Chemax, who had heard of it from Maya Indians living in the vicinity, but the trails thither were so overgrown and the distance itself so considerable, that neither Stephens nor his informant ever visited the ruins.

2. For a list of monuments presenting two Initial Series see Morley (1920:401), making a total of eight Initial Series for the six monuments.

3. Stelae 5 and 1 are the two latest monuments at Macanxoc on stylistic grounds, since they are the only two which were sculptured on all four sides, all the others being sculptured on one face only.

4. The *ukahlay katunob* from the Book of Chilam Balam of Maní states that the province of Ziyan Caan was occupied for 60 years before the Maya settled at Chichén Itzá (Brinton 1882b:95). Is this total of 60 years for the sojourn at Ziyan Caan merely the long arm of coincidence, or could Macanxoc or some place nearby have been at one time the principal center of this Province of Ziyan Caan?

5. This site was discovered in 1910 by an expedition from the Peabody Museum of Archaeology and Ethnology of Harvard University under Alfred M. Tozzer.

34.2.

H.E.D. POLLOCK

Report on the Cobá Expedition

YB 28:328–329, 1929

On February 21, Mr. Pollock left Chichén Itzá for Valladolid and proceeded eastward from there to Cobá. The object of the expedition was the examination and photographing of two newly discovered stelae. These stelae were found, and numbered 13 and 14 in accordance with the system of enumeration previously established at this site,

Stela 13 stands about 200 yards [182.9 m] east of the southeast end of Lake Cobá and about 25 yards [22.9 m] north of the main trail between Cobá and Macanxoc. Situated at the foot of a large mound, it faces south. The stela was apparently enclosed by a low wall about 10 feet [3.1 m] square with low antae projecting forward on either side of the stela proper. The outline of the enclosure is marked by a single course of stones at ground level, while within the square there is no fallen material other than from the antae and rear wall which stand approximately 2 and 4 feet [0.6–1.2 m] high, respectively. This would indicate that the enclosure may have been merely outlined at floor level, while it is quite certain that there was no roof.

The stela is in a bad state of preservation. Near the left edge a raised panel runs from top to bottom and carries the faintly visible outlines of incised hieroglyphs. At the lower right, a leg shown in profile is clearly discernible from mid-thigh to heel, which, in conjunction with faint traces of a waist and shoulder, suggests a standing figure facing to the left. Two broken parts of the stela were found and replaced, but a portion of the topmost glyph is still missing. The few glyphs are worn beyond all hope of decipherment. The monument measures 9 to 10 inches [22.9–25.4 cm] in thickness, 35 inches [88.9 cm] in width and 68 inches [172.7 cm] from the highest point to the bottom of the sculpture; the bottom 6 inches [15.2 cm] of the shaft are unsculptured.

In the process of preparing the stela to be photographed, it was discovered that it was set about 18 inches [45.6 cm] into the floor of the enclosure, and that 12 inches [30.4 cm] of sculpture were thus hidden. The low height of the monument and the existence of only 6 inches [15.2 cm] of unsculptured stone at the base point to the possibility that several feet of the lower end may have been broken off and the stone reworked to its present condition. Keeping in mind the early dates but rather late architectural types,

known to exist at Cobá, these facts can not help but suggest that the stela was set up in its present position by a later people than the actual sculptors, perhaps as a venerable object rather than a contemporaneous record.

Stela 14 is situated about 200 yards [182.9 m] south of the main trail and slightly west of due south from Stela 13. This places it on the isthmus between Lakes Cobá and Macanxoc. It is at the foot of a large mound running north and south, but itself faces southwest. In general, the local situation is similar to Stela 13, with antae on either side of the monument.

This stela is in a more broken condition than the former, and the existence of hieroglyphs highly uncertain. In the lower left corner a small kneeling figure faces to the right, while in the center is faintly, traceable the outline of the main figures with feet at an angle of 180 degrees and standing on what was probably the representation of a captive. In the lower right corner is another small figure that may or may not be in a supplicatory attitude. Between 25 and 30 broken pieces of this stela were replaced, and a large block of three parts, that pretty surely formed the upper right corner of the monument, was fitted together, but not replaced, because of the badly weathered edge of the standing section. The measurements are: thickness, 14 inches [35.6 cm] at the base, tapering upward; width, 55 inches [1.4 m]; height, 62 inches [1.6 m] from the highest point to the bottom of the relief; at least 18 inches [46 cm] below this is unsculptured.

As in the case of Stela 13, this stela was set into a floor, but all sculpture ceased at the floor level with a carved border line coinciding with plaster marks from the floor. Beneath the floor a fragment of well-sculptured stone, which did not belong to the Stela, was found, but no other fragments came to light during the digging.

Time was so limited as to prevent any considerable exploration of the site. In a reconnaissance of two hours along the isthmus between Lakes Cobá and Macanxoc, however, several interesting architectural features were noticed, and an additional stela in completely ruinous condition was discovered. The site strongly gives the impression that more stelae are, to be found here, and it is felt that this city, which apparently possesses both Old and New Empire connections would well repay more systematic examination.

34.3.

ALFONSO VILLA ROJAS

Survey of the Cobá-Yaxuná Highway

YB 32:89, 1933

The long *sacbé*, or raised highway, which originates at Cobá, has been believed to join that city with the ruins of Yaxuná, some 60 miles [96.6 km] to the west. Both ends of the road had been examined, and Captain Bennett recently traced it well eastward from Cobá, but no complete traverse had been made. This was done by Mr. Alfonso Villa during the past winter. Mr. Villa, with a force of 12 Maya Indians, left Yaxuná on February 27, and devoted three weeks to cutting his way the entire length of the *sacbé*, through to Cobá, making a measured survey and recording features of

archaeological interest encountered en route. He reports that the road is from 30 to 34 feet [9.1–10.4 m] in width and that it is raised to a height of from 2 to 8 feet [0.6–2.4 m]. It was built by erecting retaining walls of large, roughly faced limestone blocks and filling between them with rough stones, which became progressively smaller toward the surface. Its actual roadbed was finished with a smooth coating of lime plaster. For 43 miles [69.2 km] eastward from Yaxuná the road runs almost perfectly straight; in the last 19.5 miles [31.4 km] before reaching Cobá it makes five slight changes of direction. At intervals there are mounds built close to the highway, and near Cobá are several monuments bearing badly eroded hieroglyphs. At 21 miles [33.8 km] from Yaxuná was discovered a limestone cylinder 13 feet [3.9 m] long, 2.25 feet [0.7 m] in diameter, and about five tons in weight, which, it is thought, may have served as a road roller.

35.0. TABASCO AND VERACRUZ

35.1.

KARL RUPPERT

San Andrés Tuxtla

YB 37:153–154, 1938

At the invitation of Sr. Arq. Ignacio Marquina, Chief of the Office of Prehistoric Monuments of the Mexican Government, Mr. Ruppert as representative of the Carnegie Institution spent the months of November and December 1937 in cooperative investigations with Sr. Lic. Juan Valenzuela and Sr. Agustín García Vega in the region of San Andrés Tuxtla, southern Veracruz.

The greater portion of the time was spent at Matacapam and on the island of Agaltepec in Lake Catemaco. Sites near Matacanela and on the outskirts of Catemaco were examined. Matacapam comprises over 40 mounds, of which three of the most promising were excavated in part and trenches for stratigraphic collections of potsherds were made in two mounds and three plazas.

One of the mounds excavated disclosed a pyramid rising in two terraces with batter and vertical super-element. The pyramid-facing of ground lava rock and adobe clay formed a hard durable surface which has well withstood the elements. A second mound,

also rising in terraces, was definitely circular. The nature of its superstructure was not ascertained.

All material collected was sent to the National Museum in Mexico City, where Mr. Ruppert, on his return from the Institution's later expedition to Quintana Roo, spent the months of June and July with Sr. Valenzuela studying the ceramics. Distinctive local types for Los Tuxtlas were not determined. Pottery of the Red on Orange second period of Monte Alban and a Gray Ware with incised decoration similar to that of the third period of Monte Alban are relatively common throughout the various levels. Certain wares are reminiscent of the Isla de los Sacrificios, and the black painted faces of figurines common to the Huasteca also occur.

The southern Veracruz area is archaeologically almost unknown. The above-noted preliminary investigations have yielded valuable information as to contacts with neighboring localities. However, the local wares must first be identified as a foundation for future work, as they will serve to correlate this culture with those already studied or under investigation.

35.2.

ALFRED V. KIDDER
Veracruz

YB 38:242–243, 1939

A second activity carried on in cooperation with a Latin American government was the investigation of certain archaeological sites in southern Veracruz. In this Mr. Ruppert participated with Lic. Juan Valenzuela and Ing. Agustín García Vega of the Mexican National Institute of Anthropology and History.

Veracruz has always been recognized as an area of much archaeological interest. The beautiful small stone carvings and the smiling pottery heads of the Totonac country are in many museums. Large sites are abundant. But neither local cultural sequences nor relationships with other parts of Middle America have been worked out. The latter, in particular, should be important, for there must have been contacts between this rich coastal belt and highland Mexico. Furthermore, southern Veracruz occupies a strategic position as regards migrations of peoples or cultures from Mexico into Yucatán. There are, as well, striking but as yet unexplained resemblances between certain Veracruz sculptures and those of Guatemala's Pacific coastal plain.

When, therefore, the Mexican government in 1938 proposed to the Institution a joint survey of the region, the invitation was gladly accepted and Mr. Ruppert was delegated to work with the above-mentioned Mexican archaeologists.

Two seasons have now been spent in southern Veracruz, attention having been directed to the general region of Los Tuxtlas. Excavation of numerous mounds has yielded interesting data on architecture, ceramics, and stone carvings. And while the collections, especially the pottery, have not been sufficiently studied to permit definite conclusions, there is indication of connections with Monte Alban in Oaxaca, Teotihuacán in the Valley of Mexico, the Huastec district of northern Veracruz, and Kaminaljuyú in the Guatemala highlands.

At the close of the field season in June, Mr. Ruppert visited Tapachula, Chiapas, near the Guatemala border, to examine Izapa, a large and apparently important site containing a number of carved stone monuments.

35.3.

HEINRICH BERLIN
Tabasco and Campeche

YB 52:284–287, 1953

Archaeological reconnaissance in the Mexican states of Tabasco and Campeche were carried on under a Carnegie Institution Fellowship. The immediate object was to find sites of Toltec and Postclassic period occupation. As the New World Archaeological Foundation and the Smithsonian Institution were conducting researches in the southwestern and western sections of Tabasco, those areas were obviously not included in the survey.

Berlin left Mexico City January 8 and returned May 24. The field work was devoted mostly to recording sites, collecting surface sherds, and running test pits at places which seemed from previous information to bear on the problem. A short visit was paid to Mayapán at midseason in order to establish contact with the staff members of the Department working there, and at the end of the season two weeks were spent at the Mérida headquarters in making a preliminary analysis of the pottery collected and arranging its proper storage.

Field work began at Villahermosa, where the local museum was visited. The first place inspected was Cunduacan, the old Cimatan, where only a few unimpressive mounds were found. Subsequently a more important group of mounds with a definite plaza arrangement was encountered in the vicinity of nearby Huimango. More scattered archaeological mounds were seen between Cunduacan and Comalcalco at Finca Santa Rosa, Galeana and Iquinuapa. At the last-mentioned site a plaza arrangement was again observed.

Brick and mortar of lime made from burned shell were encountered for the first time as building material in mound constructions at Finca Esperanza, south of Comalcalco. At Comalcalco proper the known ruins were visited briefly. At Santa Margarita, between Comalcalco and Aldama, two *hachas*, or thin stone heads, which had been unearthed recently, were photographed.

The whole northwest coast of Tabasco is characterized by large lagoons with a great abundance of shells, suitable building material in an area which is lacking in rock. Shell was employed in the numerous mounds of the Ahualulcos ruins, which are on an island among swamps near the Santa Ana River. Pieces of pottery of fine, Late Classic finish, now in the museum at Villahermosa, are reported to have come from this site. Random sherds collected there would sug-

gest, however that the occupation at Ahualulcos started, in Preclassic times, and that it may well have continued into the Postclassic period.

Subsequently the ruins of Bellote, discovered years ago by Désiré Charnay, were examined during a stay of two weeks at the site. The mounds cover about half a square kilometer, and in several of them the use of shell as building material was noted again. Most of the work was devoted to the mound where Charnay had excavated previously. The debris of the older excavation on top of the mound was removed in order to establish the outline of the temple (?) platform. Charnay's statement that it represented at least three or four periods and that brick was used could be confirmed. An isolated stucco glyph was found on the middle construction, and an Ik glyph within a stucco medallion on the most recent one. Thus the platform walls had classic Maya decoration on the southern façade on both sides of the stairway. The occupation of the site, however, must have begun earlier and have lasted considerably longer. A pit dug into the mound fill of shell yielded, beneath a sealed floor, one Chicanel-style bowl and a coarse incised vessel. Another pit at the base of the same mound led to the discovery of a multiple grave full of large storage vessels, which were only partially excavated. Most of them were arranged in pairs, one serving as cover for the other. These crude vessels are for the moment not diagnostic, but the fact that they were accompanied by a Fine Paste Ware vessel and probably were associated with an unmistakable Fine Orange jar would suggest that the time of the grave was near the end of the Late Classic or even in the Postclassic period. Surface sherds collected at Bellote and at the nearby island of Francisco Chable confirm the postulated long occupation.

The coastal strip east of the lagoons is slightly raised over the southern swamps and thus provides permanent dry areas on both sides of the mouth of the Grijalva River. It is not surprising, therefore, that we find here many testimonials of pre-Spanish occupation. A more or less continuous row of mounds extends from Chiltepec to Frontera. At Hacienda El Coco the owner had trenched one of these mounds; an additional trench was made in the same mound by Berlin during a three-day stay. It disclosed the existence of two superimposed structures of walls of mortar simply spread over the earth fill. Few sherds were found, but as the owner had kept the pottery collected in the first trench, mostly Fine Orange Ware, this could fortunately be photographed. At the modern village of Juarez the group of mounds illustrated years ago by Berendt was identified.

Mounds continue along the east side of the Grijalva River, and the following sites were visited: Las Minas, El Zapotal, Concepción, and El Encanto. The last-men-

tioned place is on the left bank of the San Pedro y San Pablo River. At Las Minas, as well as at El Encanto, the use of brick was again noted.

Farther east, in Campeche, a visit was made to the site of Atasta, where in 1944 M. W. Stirling had seen interesting sculpture and stucco work. Preliminary digging resulted in the discovery of a carved stone tablet of poor workmanship showing a prowling jaguar (?). Another sculpture, which belonged to a farmer and showed a human head in the jaws of a snake, was photographed. Considering all the sculpture so far found around Atasta plus some which is in the local museum of Ciudad del Carmen, it becomes evident that we are dealing with a local school of sculpture which is completely different from the classic Maya and which is difficult to classify at present. A copper point found in our trench at Atasta suggests a late occupation of the site.

East of Laguna de Términos a newly reported site 3 km west of the railway station of Escarcega was visited. Material for road building had been taken from the group of mounds, and two building phases were exposed in one of them. Well cut stones were used in the older phases; the temple platform had inset corners, and the stairway was divided at the highest step into two sections by a protrusion of the temple platform.

In Tabasco again, the site of Tiradero was visited. E. W. Andrews had reported abundant Preclassic, pottery there in a railway cut. No excavation could be made in the center of the mound where the road had cut through, because no permit could be secured. A pit dug near by produced Chicanel material. It could further be established that this particular mound belongs to a vast archaeological site located in one of the bends of the San Pedro Martir River. A broken plain stela was found on the main plaza. A pit dug near the stela did not result in the finding of expected floors, but the pottery encountered showed Preclassic material throughout and a few Fine Orange and Fine Gray sherds in the upper levels. No standing buildings were observed, but in at least one of the mound groups their former existence seems very likely.

After a two days' visit to Palenque, the lower course of the Usumacinta River was surveyed starting from Tenosique. Mounds were noticed between Tenosique and Balancan at Guanál, Estapilla, Canizán, Multe, and Santa Ana.

South of Balancan, the important site of Arenitas, first reported in 1951, was visited. Arenitas has a huge main plaza 150 by 50 m with single mounds at the ends the long axis, and rows of mounds along the sides. The large single mound at the north end of the plaza is about 18 m high; the stairway faces south, and several of the exposed steps show good workmanship in cut

stone. Pieces of stucco decoration and wall fragments are scattered along the bases of the mounds. If excavated, the site will undoubtedly prove to be of major importance.

Farther down the Usumacinta, Emiliano Zapata, mounds were observed at Tierra Blanca and Corral Nuevo. At the first site the owner of the ranch there had collected a few archaic figurine heads. Below Emiliano Zapata an excavation was made near the mounds of Tecolpan on the left bank of the river. Abundant Fine Orange pottery was found together with fine classic Maya figurine heads. At a nearby cut of the river at Rancho El Tren some Preclassic and Early Classic Maya sherds were collected. The Tecolpan region may well yield a continuous stratigraphic sequence of Maya pottery of the Tabasco plains.

The island of Chinal, near Jonuta vaguely mentioned by Charnay, was partly explored, but only some low mounds with a few pre-Spanish sherds were found at Rancho Pajalal.

In the mounds of Jonuta much brick-work was noted, employed in the usual fashion as facing for the pyramids with a final cover of shell mortar. North of Jonuta along sand mounds were found alongside the Usumacinta at Ramonal, Quien Sabe, Sitio Nuevo, Paraiso, and Encarnación and another brick mound at Finca Oaxaca on the San Pedro y San Pablo River.

The last two sites to be visited were Tamulte de las Sabanas and the ruins of Tortuguero. Tamulte de las Sabanas is a Chontal-speaking village. In the outskirts in a nearby barranca, there is a place of worship with about five natural sandstone rocks where pagan offerings are still made, such as lighting of candles or pieces of wood, killing of birds, ritual eating, and drinking of aguadiente. Only men perform these rites.

In company with Carlos Pellicer, director of the local archaeological museum of Villahermosa, the ruins of Tortuguero were visited. Since Blom's visit the tailpiece of Stela 2 has been broken off, but with the help of a newly found fragment, it was possible to identify the present two fragments of the stela, the new piece, and the plain shaft referred to as Monument 4 by Blom as being a single work of sculpture. In the plaza where Monuments 2, 3, and 4 are scattered, a new small carved stone fragment was discovered and called Monument 5. On one side an Initial Series is still visible, inscribed with bar and dot numerals. The baktun coefficient is clearly 9 and that of the katun between 12 and 15, 14 being most probable. The other glyphs are too weathered to establish a definite reading, but 9.14.10.0.0 5 Ahau 3 Mac is suggested as a possible solution. Nothing of the design on the front could be made out, with the exception of two parallel rows of three glyphs each. Only the numerical coefficient of 3 in C1 and of 8 in C2 could be deciphered.

A fallen stone column was found approximately 100 m south of this plaza. It is more than likely that more sculptures will be discovered at the Tortuguero ruins, once the forest, which now covers almost the entire site, has been cleared.

35.4.

HEINRICH BERLIN

Tabasco and Campeche

YB 53:293–295, 1954

As the surface collections of the previous field season in Tabasco had revealed a great abundance of Fine Paste Wares (including Fine Orange), the 1954 season, again under a Carnegie Institution fellowship, was devoted to carrying out excavations at six sites representing Late Classic and Postclassic horizons, in order to obtain larger and stratigraphic samples of this important material. Berlin was in the field from January 11 to April 15. Until February 27 he was accompanied by Carlos Navarrete, a student of the Escuela Nacional de Antropología e Historia of Mexico City, with whose assistance it was possible to run a greater number of test pits.

At the beginning of the season the ruins of Palenque were visited. The director of the local school at Palenque village possessed a painted stucco glyph which he had found at the temple of the nearby site of Xupa. Thus it seems likely that the piers of this small temple had stucco inscriptions in the fashion of the Palenque temples, a fact which had escaped all previous visitors. A careful search at the foot of each pier should result in rewarding finds.

The first dig was done at Tecolpan, below Emiliano Zapata, on the left bank of the Usumacinta River. Pits were opened at several places near the base of the main pyramid, in the surrounding swamps, and on an elevation in the swamps. Only a few surface sherds were found in the swamp pits, probably coming from backwash from the main group. This absence of sherds in the swamps is evidence that in prehistoric times this region already was swamp and therefore not inhabited. On the other hand, in the pit on the elevation, probably a house mound, sherds were found almost to the ground-water level. The digging around the main pyramid duplicated the findings of last year. Several burials were encountered in the various test pits, but

none was associated with any ceremonial offering, nor was there any consistency in their orientation, though supine position was predominant.

At nearby El Tren a few Preclassic and Early Classic sherds had been picked up last year. This season, unfortunately, only one day could be devoted to the making of a hasty test pit. It yielded a high percentage of Early Classic material, showing in the polychrome ware notable similarities in design and color to the Petén material of the same epoch. Yet in the Late Classic pottery of Tecolpan, Tepeu-like polychrome is virtually absent.

The Late Classic fine paste horizon was met again at Jonuta. The character of the deposit and stratigraphic situation there are peculiar: a black, 1 m thick layer, heavily packed with sherds, emerges from the Usumacinta waters just northeast of the town and, after gradually rising for 30 m, reaches the top of the right bank, continuing southwest for several hundred meters. It is in this layer that the famous Jonuta figurines occur. A fine collection of figurine heads, mostly belonging to whistles, in the possession of Sr. Omar Huerta was photographed. Despite the great variety, recurring types could be recognized and classified into major groups. In a subsequent visit to the local museum of Villahermosa, several Jonuta subtypes were identified in the figurine collection on exhibit.

At this museum are housed all monuments of the Tortuguero ruins, brought there, since last year. They can now conveniently be studied. In addition to the monuments already known, two hitherto unknown fragments were brought to the museum. These are Monument 7, the trunk of a statue of which only the back is in fair condition; and Monument 8, probably the lower part of a standing sculpture. The first is similar to Monument 3.

The sherds excavated at Huimango in the Cunduacan district seem to belong to the Late Classic Jonuta horizon. Fine Paste Ware at Huimango, however, is more of gray variety than of the accustomed orange.

Another site where excavations were undertaken was Juarez in the Cintla region close to the battlefield where Cortés, his famous victory over the Indians of Tabasco. The top of the main mound was cleared and much ceremonial ware recovered, such as fragments of incense burners, ladle incense burners, small Atlantean figurines, and clay models of temples. Human faces and general workmanship are extremely crude. The associated fine paste wares show almost no decoration and are radically different from the ones found at Tecolpan and Jonuta. All the material was concentrated on the rear of the top platform of the

mound and was covered only with an insignificant layer of humus. Evidently it represented the last offering deposited there before the site was abandoned as a religious center. As no more recent material has been found so far in this region, we can hardly be wrong if we interpret the Juarez pottery as belonging to the last few centuries prior to the conquest.

A similar situation was met at Tamulte de las Sabanas. On the rear of the top platform of the main mound of a major group, ceremonial and fine paste wares again were encountered, and in this case associated with copper bells, a definite proof of relatively recent age.

In the modern village of Tamulte there still exists a local tradition of pottery making, done by women only. This pottery is not-traded outside the village. Besides the normal ollas, comales, and so on, they make potstands (called *met* in the native Chontal language) and heavy-walled tubes (*xun*), which are used three at a time as firestones, a suitable substitute in a region where stone is completely lacking.

Finally, at Atasta (Campeche) a very low platform was excavated and a small earth mound trenched. On the platform was a modeled stucco jaguar, which had formed part of its decoration. The façade of the mound was built only of stucco without the use of any stone. At the center two legs of a person in dancing attitude were still recognizable. In front of it was a small round altar platform, the walls of which were also done in stucco.

The trenching of the mound resulted in the discovery of two minor graves, one at the level of its foundation, the other near the top of the mound. The ceramic material recovered from both graves belongs to the same epoch, the previously established Postclassic fine paste coastal horizon. One should bear in mind, however, that the excavations at Atasta were limited to a few acres and that the real history of the site and its immediate neighborhood probably extends over a much longer period of time.

The excavations of 1954 in Tabasco have revealed two fine paste ware horizons. One is Late Classic and centers around Jonuta, where it is associated with beautifully executed Maya figurines. The other is Postclassic or even Protohistoric and is found along the Tabasco and southwest Campeche coast. One is tempted to ascribe this last material to the Chontal-speaking tribes which inhabited the Tabasco coast at the time of the conquest and still inhabit part of it. The change in the aesthetic concepts may be due to the influence of foreign groups producing a stimulus which the coming of the Spaniards prevented from developing a fresh art style.

36.0. YUCATÁN

36.1.

ALFRED V. KIDDER

Archaeological Work in Yucatán

YB 34:123–126, 1935

As was stated in the last *Year Book* report [Chapters 1.22 and 1.23], the 10 years of intensive excavation at Chichén Itzá are being followed by an interval for the publication of those units of work which have not yet been treated monographically; and for research upon certain problems raised by the Chichén Itzá diggings which can not be solved save on the basis of investigation elsewhere in the peninsula. The Institution's headquarters at Chichén Itzá have, however, been kept open to serve as a base for the field-workers. Dr. Morley was, as usual, in residence. He devoted his time to preparation of his compendious report upon the inscriptions of the Petén, and to further studies, in collaboration with Mr. Roys and Sr. Rubio Mañé, upon the history of the Xiu family, former rulers of the city of Uxmal.

Several conferences were held at Chichén Itzá during the spring, when new material gathered by Messrs. Roys and Rubio Mañé was compared, collated and combined with data collected in previous years, and many gaps in the story of this most interesting and ancient family were filled. Sr. Rubio Mañé made

an extensive search of all church records in the Xiu region for items concerning the Xius; it is felt that when he has completed his examination of the 250-odd notarial books in Mérida, practically all known sources for Xiu material will have been exhausted. Dr. Morley also excavated a mound near the town of Oxkutzcab, for the purpose of locating, if possible, the site of the church of the former Maya village of San Juan Bautista Yaxacumche, where the Xiu family lived during the Colonial Period.

The mound lay about 50 m east of an old Spanish well, still known by the name of San Juan; and this fact, together with its location on what had been the east side of a plaza, the proper position for a Roman Catholic church, indicated that it might be the remains of the former church of San Juan Bautista Yaxacumche.

The excavations disclosed a foundation mound some 40 m long, 30 m wide and 2 m high, its longitudinal axis east and west, its east, north and west sides faced with, four courses of masonry arranged in retreating steps, like the narrow-treads of a steep stairway;

these treads were about 15 cm wide. On the south side they are so much wider (1.5 m) that it would seem the mound originally faced in this direction.

Traces of a plaster floor could be distinguished here and there about 30 cm above the top of the fourth course of masonry on the east, north and west sides. There was so little debris above this floor level and what there was contained so few stones, being composed mostly of earth and lime plaster residue, that it was evident there had never been a masonry superstructure. On the other hand there was sufficient debris to indicate a former superstructure of saplings and thatch, its walls perhaps daubed with mud or lime plaster.

The excavations yielded a considerable quantity of potsherds, but no whole or even restorable pieces. These were examined by Mr. H. B. Roberts, who reports that 80 percent are of common wares, which throughout the prehistoric and historic periods show no marked change and are therefore of little value for chronologic determinations. The remaining 20 percent were of a type unknown to him, though he felt that they might be allied to the wares of the Puuc region.

The excavations established that this mound was not the remains of a Roman Catholic church, but whether it dates from before or after the Conquest could not be settled by the evidence at hand. When the significant 20 percent of the ceramic remains shall have been identified, its chronologic position will be clearer.

THE ARCHITECTURAL SURVEY

The purposes of the Architectural Survey have been outlined in earlier reports [Chapters 2.1 and 2.2]. It was there pointed out that the architecture of the Maya was a highly important part of that culture and as such might be expected to reflect the growth, development and general course of Maya civilization. In its broader aspects, then, the Architectural Survey is to be regarded as a step toward the reconstruction of Maya history. More specifically, its aims are the determination of cultural and ethnic movements and the establishment of time sequences as reflected in architecture.

At the start of operations in 1932, the hill region of Yucatán, known as the Puuc, was selected as the initial point of attack. This was done primarily because of the large aggregation of comparatively well-preserved buildings that occur in the area, and secondarily because of the relative ease of access to these ruins. It was thus believed that at the outset the survey might amass a considerable body of data that should serve as comparative material for further work. While the Puuc ruins were to be the starting point for comparative architectural study, certain other sites in Yucatán that held promise of considerable importance, and thus, might be termed strategic in indicating architec-

tural trends, were noted as prospective localities for work in the near future. During that season operations were carried on at the large site of Labná and at several small sites in the Sabacché region of the Puuc, the season being brought to a close with work, at the strategic site of Yaxuná in the center of the peninsula.

The Architectural Survey did not enter the field in 1933 but returned to Yucatán late in the autumn of 1934. A continuation of the study of ruins representative of the Puuc region was the main objective, and work at the large sites of Sayil and Kabah occupied the greater part of the season. A certain amount of work was also carried on at the ruins of Holactún in the savanna of Xcalumkin in Campeche, and a brief visit was paid to the Maxcanú region, notably to the ruins of Oxkintok. In addition to the strictly architectural work of the earlier season, the sites of Sayil and Kabah were mapped, a sketch map was made of that part of the Xcalumkin savanna that includes the ruins of Holactún, and observations were taken to determine the geographical coordinates of the sites of Labná, Sayil, Kabah and Holactún.

Reviewing the results of the survey up to the present time, it is felt that certain facts dealing with the environment of the Puuc region, or more precisely the effect of the environment upon the ancient culture, are beginning to be understood. It is, for example, interesting to note that a region which probably harbors more known remaining than any other area in Yucatán appears to be the most fertile agricultural region in the peninsula; also that due to an almost complete absence of natural water supply the inhabitants resorted to the artificial storage of rain water in underground cisterns, known as chultunes, and that great numbers of specialized, platform-like structures were created for this purpose. Turning to matters pertaining more strictly to building remains, the ruins of Labná, Sayil and Kabah exhibit a certain uniformity of plan in that each possesses an artificial causeway, or *sacbé*, with a general north-south axis and with important buildings or groups of buildings at each terminus. There is, moreover, some reason to believe that intercity causeways may have existed, one connecting Kabah and Uxmal being a distinct possibility.

Construction practices have been studied and thoroughly recorded, and a large amount of decorative detail, both architectural and monumental, has either been discovered or has been recorded for the first time.

In attempting to evaluate the work of the Architectural Survey in Yucatán, it is felt that real progress has been made toward the original objective of collecting a body of architectural data to serve as comparative material for further work. An obvious lacuna in the knowledge of Puuc architecture is found in the absence of an adequate architectural study of the out-

standingly important city of Uxmal. It is hoped, however, that this will shortly be filled by publication of the extensive researches made at the site by Tulane University. It is also highly desirable that a rapid reconnaissance be made of a number of lesser sites in the Puuc. All the information thus far collected confirms the previously existing belief that the architecture of the region is remarkably homogeneous. It has thus been extremely difficult to discern architectural trends and developments within the area. Due to the scarcity of superposition of buildings that yield information without resorting to excavations beyond the scope of survey work, it has also been hard to interpret architectural styles in terms of chronology. These difficulties suggest that the survey must pay increasing attention to distribution of architectural types as opposed to stratigraphic sequence at any one site.

The small amount of work that has been carried on outside, or on the borders of the Puuc has led to rather different results. While there is a woefully small amount of architectural data preserved at Yaxuná, there is every reason to believe that two types of construction, one of them linked with the Puuc and each representing a different time period, occur there. Somewhat similar conditions seem to be present at Oxkintok, judging from a brief inspection of those ruins. The remains at Holactún-Xcalumkin, on the other hand, do not suggest two or more clear-cut periods of occupation but rather an unbroken development of architectural style that appears closely related to that of the Puuc.

It thus seems that the greatest opportunities for observing architectural development and for arranging architectural styles in time sequences lie outside the Puuc. In spite of that fact it is not believed that the relatively intensive work carried on within the area has been wasted. The homogeneity, possibly even static quality, of Puuc architecture makes it an admirable norm with which other types may be compared. It is probable, moreover, that only through a fairly complete knowledge of this architecture will developments in other regions be intelligible.

36.2.

E. WYLLYS ANDREWS

Yucatán

YB 41:257–263, 1942

It is curious that the most heavily populated and geographically best-known section of the Yucatán peninsula

has remained almost entirely unstudied by the archaeologist. The ruins on the low plain to the north of the Puuc hills and to the west of Chichén Itzá are represented in scientific literature by only the briefest references.

During a stay in Yucatán from December 1941 through June 1942, Mr. Andrews carried out preliminary studies at 10 ruined sites within a radius of 40 km from Mérida. At three these, Mr. Brainerd undertook stratigraphic excavations for pottery, and at certain others surface collections were made and subsequently examined by Mr. Brainerd.

Perhaps most interesting of the season's finds was a group of sites indicating widespread, architectural activity in northern Yucatán during early Old Empire times. These illustrate a style of temple architecture rigid in itself and distinct from the elaborate patterns of later pre-Mexican construction on the northern part of the peninsula. The chronological separation of the distinctive early and late styles is attested by actual superposition of buildings, the occurrence of transitional forms, and the association of distinct pottery types with the two architectural styles.

The early architecture is distinguished by a special structural technique. Wall masonry is of large, roughly faced blocks, leaving little or no space for cement hearting between the two faces. Vaults are of deeply tenoned flat slabs, apparently never pre-shaped, set in roughly corbelled courses with much fine rubble and cement. Wall faces are evened with considerable spalling, but vault faces are composed entirely of it, as the crude ends of the flat slabs offer no regular surface. Wall and vault surfaces were finished with a thick coat of plaster. Neither wall nor vault shows any suggestion of veneer.

The form achieved is both constant and simple. Basal moldings either are absent or are composed of a single course of rough blocks. Medial and superior moldings consist of a single rectangular member. The upper façade is normally covered with stucco designs in deep relief, which often extend onto the moldings. Carved stone is never used in façade decoration.

Later pre-Mexican architecture of the region is characterized by the use of very finely shaped and faced stone in a thin veneer a rubble core, both in wall and in vault. No spalling was needed, and a thin coat of plaster sufficed to form a very smooth surface. Basal moldings, usually complex, are almost universal. Medial and superior moldings follow a three-member pattern, the upper and lower elements triangular in section. The upper façade is characteristically heavily adorned with mask panels or a variety of designs made of up of mosaic small carved elements, where stucco relief is found, it is secondary.

Excavations in a small section of the acropolis at Acanceh revealed that the famous temple with the

stucco reliefs belongs to the earlier pattern. It was originally built close to the north edge of a truncated pyramid about 8 m high. Later, the platform was extended some 60 cm, and a new face added to the pyramid, the sides of which were covered with white stucco and painted with designs in red. A further stage of construction extended the platform a considerable distance farther north; and on this addition, some 50 cm above the original floor level was built the long, narrow building facing the Stucco Temple. The new edifice, although retaining the essential block-wall and slab-vault structural technique, varied somewhat in external form. It stood on a 35 cm tall, single-member basal molding, and although retaining the simple rectangular medial and superior moldings, replaced the strongly, retreating upper façade of the Stucco Temple with a taller vertical one. Excavation showed that during the use of the court between these two structures, the floor level was raised five times. Finally, temples were filled with rubble, their doorways were sealed with masonry of the early type, and the entire area was filled in to the level of the roofs to serve as foundation for buildings in the later architectural style. This final phase is represented by no standing rooms on the acropolis, but is evident from an abundance of carved stone façade ornaments, typical veneer wall blocks, finely cut, deeply tenoned vault stories, and full-width doorjambs. Associated with each of the developmental phases mentioned were sealed deposits containing potsherds which should be correlatable with Brainerd's more extensive stratigraphic material from the slopes of the acropolis. A preliminary examination indicates the probability that all stages through the filling-up of the court between the two early temples belong to pre-Puuc times. It is probable, moreover, that the large pyramid in the city plaza, originally covered by a later structure but now considerably exposed, also belongs to the early horizon. Visible fragments are characterized, by the use of inset stairways, rounded, inset corners, a lack of finely cut stone, and the use of large panels of stucco relief. The plan is strongly reminiscent of that of early Petén substructures.

As early as 1911, Seler suggested that the buildings at Acanceh were earlier than those generally known in Yucatán. He also pointed out a strong resemblance between Acanceh architecture and that of Aké and Izamal to the north, and suggested that the latter sites might be assigned to an early period. Acanceh and Aké, both large ruins, are conspicuously ignored in the conquest-period historical traditions of the local natives. Landa states in regard to Izamal, "There is no remembrance of their builders and they appear to have been the first." During the present season, brief visits were made to Izamal and Aké. The majority of remains at both sites are definitely not in

the Puuc tradition, which is easily recognizable even in the debris of wholly fallen buildings. Nor do they consist of the entirely uncut stone whose use followed the abandonment of fine veneer in Yucatán. Substructures and, in some cases, buildings were made of great, roughly faced cubical blocks differing only in size from those of Acanceh and other early sites. The stucco decoration of the Izamal pyramids is remarkably similar to that of the mound in the plaza at Acanceh. Finally, Brainerd states that sherds from below the plaster floor of one of the final additions to the mound complex south of the Convent of San Antonio at Izamal are referable to the basal-flange horizon in the Petén. This reference is paralleled by the orderly distribution of ruins at Aké around rectangular plazas, an arrangement characteristic of the Petén sites but not found in the cities of the Puuc and Mexican horizons in Yucatán.

Evidence that these differences are chronological rather than geographical is to be found at Cuca, 10 km east of Aké. Here the remains are entirely of buildings in highly evolved Puuc style with no trace of the megalithic or block construction discussed above.

Ten days were spent at the ruins of Dzibilchaltún (also locally known as Xlakah), 15 km north and slightly east of Mérida, where Brainerd was conducting ceramic excavations. One standing temple there belonged clearly to the early style both in structural technique and in external form. But a number of minor traits hinted a possible developmental transition to the Puuc style. The structure had a low basal molding, and the wall stones were more finely cut than those of Acanceh, although showing no tendency toward veneer. The spring course of the vault was of very carefully faced stone, in strong contrast with the rough slabs of the vault itself. The end walls carried a thin false vault spring, a characteristic of Puuc architecture found in neither of the early temples at Acanceh. Pottery from between two floors in one of the rooms has tentatively described by Brainerd as immediately antedating that found in the Puuc sites. This earlier architecture seems to have included the greater part of the construction at Dzibilchaltún. Visible fragments of a filled-in and almost completely buried structure in another part of the site show identical masonry and outer façade form, and indicate that at least large parts of an elaborate stucco façade similar to that at Acanceh remain intact under later construction. Other lower wall and vault fragments are in this tradition, and the general plan of the site is characterized by Petén like aggregations of mounds around orderly plaza systems. However, a few carved façade stone elements strongly reminiscent of Mexican-period Chichén Itzá art bespeak at least, some later occupation. These remains are very common in a single court at the eastern edge

of the site, and rather rare elsewhere. Although a number of glyphic stelae are too badly damaged to offer any hope of translation, it is clear that none carried Initial Series.

About 40 km west and slightly south of Mérida and 6 km southwest of Kinchil are the ruins of Tzeme, a very large site covering several square kilometers. A large part of the town of Kinchil and the neighboring hacienda of Santa Maria have been built with stone taken from its monuments; and two grotesque life-size human statues from Tzeme have been removed to the Mérida Museum. Although no standing buildings remain, two periods of occupation are evident. At the center of the site is a group of tall pyramids around a rectangular plaza. Near by are several groups of lower pyramids similarly arranged around smaller plazas. Atop these mounds are vestiges of small structures in the block-wall and slab-vault tradition, entirely lacking carefully cut stone. In the center of the plazas, however, and scattered outside the central area, are numerous remains of distinct rubble and veneer structures with carefully squared full-width jambs, specialized vault blocks, and a variety of sculptured façade elements. These buildings clearly belong to either the Puuc, or the Chichén Mexican period.

Reports were received of the small site of Chuhkú about 15 km southeast of Tzeme, containing at least one well preserved standing temple. Many residents of Kinchil can serve as guides.

Through the kindness of Don Fernando Cervera, it was possible to spend a number of days at the large ruins on the Hacienda Yaxcopil, 25 km south and slightly west of Mérida. The ruins, about 1,500 m east of the hacienda buildings, seem to have been occupied from very early times through the Puuc and Chichén Mexican periods. Although no excavation was undertaken, much pottery from the latter periods was found on the surface. A small amount of red lacquer ware may indicate a short overlap into the last phase of pre-Spanish culture, or a small continuous population in that era. The central group of ruins is distributed around a long, narrow plaza, at one end of which is a pyramid approximately 12 m high, ascended by four stairways. Atop the complete ruin of the superstructure is a geographical bench mark with the legend N 20 degrees 45'05", W 89 degrees 42'18". This large mound is called *Tanmul*, meaning "Central Pyramid," by which name the site is occasionally known. Present superstructure debris in the central group is characterized by a quantity of veneer stone, but this may be of secondary origin. About 250 m south of this complex is a large, low platform mound bordered by four ranges of room's surrounding a central court. Several rooms of the northern range are still standing and locally called *Aka'na* (House in the Dark), by which

name the whole site has also been known. Several phases of construction are apparent. An original 5-room structure was built in style clearly transitional between the early and Puuc periods. The lower walls are faced with a poorly cut, irregular veneer, but the vault is made of flat, almost unfaced, blocks so crudely set that the face consists largely of spalling. Moldings are complex but still rectangular in section, varying in form as a support for elaborate channels of deep relief in painted stucco which covers the upper façade zone. There is no carved stone. In two later stages, a series of rooms was built around this unit in a very different manner. Their rubble walls bear a thin veneer of finely cut, beautifully squared stone laid in perfect courses. Vaults are of the characteristic "boot-shaped" and beveled blocks, equally carefully set; and the upper façade zone was covered with panels, and masks in carved stone mosaic. The outer corners bear on each face a line of carved rosettes from medial to basal, molding. The doors, simple in the interior structure, become triple, with jambs and round pillars carved in typical Puuc style. The *Aka'na* will richly reward future excavation, for in the construction of the later rooms, the stucco façade of the older temple was carefully sealed in and remains largely intact. Remains of the later Puuc period architecture are distributed generously over the site, as are those of the following era of Mexican influence. Several long, low mounds bear a central row of altars formed of crudely cut megaliths, and have no trace of further masonry superstructure. Another common form of building is the round-columned, flat-roofed colonnade of Mayapán type, whose walls (as at Mayapán) are of crude block rather than veneer masonry. This fact, in connection with the small amount of red lacquer ware in surface pottery, indicates Yaxcopil's importance for future study as possibly spanning the gap between the veneer tradition of the Puuc and Chichén Mexican periods and the uncut block masonry which later replaced it. This possibility is not known to exist at any other site on the peninsula.

Minor excavations were undertaken at one further ruin apparently occupied in pre-Puuc times. This site, 500 m east of the Mérida-Uxmal highway at Kilometer 39.5, is on the hacienda of Sihunch'en, whose name it has been given. Recently there were a number of standing buildings, but these have been in large part demolished and their stone ground up to resurface the nearby highway. Fragments of two buildings were left, both of which seem to be in the earliest architectural tradition. Walls are of large, coarse blocks with no rubble fill, vaults of the familiar unprepared flat slabs. No basal molding was used. Medial and superior moldings were one-member and rectangular. As usual, a lack of cut stone accompanies an elaborate

stucco façade, in this case largely fallen. One building had but a single long, narrow room, colonnaded in front with very crudely rounded stone columns without pedestal but with a roughly squared capital, on which rested very crude stone lintels. The total door height was only 122 cm. Masonry in both buildings is much cruder than any observed elsewhere during the present season. It may reflect relative antiquity, or merely a lack of architectural skill at this small site. Not enough pottery was found to offer much clue to dating, although a few sherds were of pre-Mexican slate which could be assigned to either Puuc time or slightly before.

Another period of Yucatán history came under study in the course of a month's work at the ruins of Mayapán. Eight buildings were either largely or entirely cleared; and a number of minor excavations served to round out the picture thus obtained. The site and its surrounding wall were mapped by Patton in 1938 [Chapter 1.27].

A minor early occupation of the site is indicated by a number of re-used, finely cut stones in the buildings of the central group. No structures of this period remain, however, although it is possible that an unexcavated interior building immediately below the present superstructure of the Pyramid of Kukulcan (Structure 10) may belong to that horizon. These remains probably correspond to an underlying stratum of pottery (about 8 percent of the whole) found by Brainerd to be similar to that of the Mexican period at Chichén Itzá.

The vast majority of remains at the site consist of small unit shrines and colonnaded palace-type structures employing either thin-drummed round columns or anthropomorphic supports for flat beam and mortar roofs, as did a few atypical structures whose plans were almost certainly copied from Chichén Itzá prototypes. The resemblance of the large round tower at Mayapán to the Caracol at Chichén has often been mentioned. The latest superstructure of the great pyramid at Mayapán is identical in plan with the Chichén Castillo, although very differently constructed and with unvaulted roof. Two small round temples excavated had ground plans similar to that of the Casa Redonda at Chichén.

Except where a few stones were re-used from the earlier period mentioned, both walls and vaults at Mayapán were constructed of completely uncut, rough blocks, with no tendency toward veneer. No prepared outer face is recognizable on blocks in fallen debris, and the absence of cubical form made coursing next to impossible. Although no façades at Mayapán stand as high as the medial molding, it is evident from debris that the profile was normally that of a single two or some time three-member molding with restricted

upper zone, and the elaborate carved stone-mosaic so typical of earlier period façades was absent.

The major occupation of Mayapán may be clearly assigned to a period later than that which at Chichén Itzá is represented by the architectural efforts seen at the ballcourt, Castillo, Temple of the Warriors, and related structures. But certainty as to whether architectural effort had entirely ceased at Chichén during the Mayapán period must await the discovery of specific associations between certain late structures at Chichén (the Temple of the Initial Series, the Temple of the Interior Atlantean Columns, etc.) and deposits of pottery from one of the two periods. Although certain of the larger temples at Mayapán undoubtedly drew inspiration for their plan directly from Chichén, the constructional techniques of the six sites are uncompromisingly distinct. The earlier veneer traditions persisted at Chichén through the end of architectural activity. On the other hand, the relation between Mayapán and the cities of the east coast of Yucatán is unmistakably close. Structural techniques are almost identical, and parallels in external form are striking. Both groups emphasize the colonnaded palace with round columns and anthropomorphic roof supports; and the simple unit shrines which form a large part of the structures in the two groups follow closely in the same plans. The lack of carved stone façade decoration in the two areas parallels the restriction of the upper façade zone and simplification of the molding pattern. Other details such as walls surrounding the cities (Mayapán, Xelhá, Tulum) imply further connection. It will be seen in Brainerd's report that available ceramic evidence equally strongly indicates that the so-called "Mexican Period" remains at Chichén Itzá form a horizon earlier than that of Mayapán and the East Coast cities. The above considerations suggest that the conventional division of peninsular culture into a "Maya Period" and a "Period of Mexican Influence," by no means delineates the significant phases of its development. In the evolution of art, architecture, and ceramics, three quite different divisions seem clearly indicated by data now available:

1. The earliest architecture in Yucatán is characterized by walls of large, crudely faced blocks, vaults of flat, entirely unprepared, corbelled slabs, and a complete absence of carved stone façade decoration. Rough wall and vault faces were smoothed by a thick coat of stucco, which was also used in the execution of elaborate reliefs in the upper façade zones. This period of occupation is seen at Cobá in the east, and is strongly represented in the Mérida region. Pollock and Shook have described contemporaneous and very similar architecture at sites running from Maxcanú in the Puuc to Bacná in central-western Campeche. Brainerd characterizes associated ceramics by absence of evolved

slateware, and affinities with Tzakol and perhaps Tepeu 1 in the Petén. The lower limits of this occupation are at least as early as the end of Cycle 8.

2. Sometime in the second half of Cycle 9, a drastic change took place in north peninsular culture. From block-wall and slab-vault architecture, there was a sudden transition to rubble construction covered by only a thin veneer of finely cut stone. The simple external building form gives way to the complex but rigid patterns associated with the architecture of the Puuc region, where the new forms may have developed. The stucco façade was replaced by elaborate panels of carved stone mosaic. Along with this change in architecture came an equally striking development of slatewares in pottery; the earlier wares disappear, and ceramic resemblances to the Petén are confined to tenuous similarities to Tepeu. This new culture does not seem to have been of foreign introduction, for the new architectural and ceramic forms had their origins in the previous period. Early in Cycle 10, continental Mexican influences appear at Chichén Itzá, either coincidentally with or shortly after the abandonment of the Petén cities and those of the Puuc. During the so-called Mexican period at Chichén Itzá, these influences altered the superficial aspects of local culture, but notably failed to affect to any extent the fundamental architectural, sculptural, or ceramic techniques. Architectural innovations are seen in such features as replacement of the basal molding by a battered lower

zone, and the prominent use of serpent columns and stairway balustrades. But the basic construction of rubble buildings with a thin stone veneer remained unchanged until the abandonment of the site. New religious motifs in sculpture accompany no great change in style. Finally, although imported trade pieces make their appearance in connection with changes in shape and design in local pottery, slatewares maintain undisputed dominance.

3. The second great change in Yucatán culture took place about the middle of the fourteenth century, and was quite as radical as the first. Veneer was abandoned, to be replaced by the use of uncut, rough blocks in a masonry more similar to that of modern native houses than to any earlier archaeological remains. Vaults are made of crude masonry, but are no more frequently used than the flat beam and mortar roof. A new temple form, the unit shrine, becomes numerically dominant. The colonnaded palace, which first appeared late in Period 2, takes on new form. Columns become universally round rather than square, and anthropomorphic roof supports are common. In sculpture, forms appear which bear little resemblance to previous artistic efforts of the Maya. In pottery, the slatewares vanish, to be replaced by what Vaillant called "Red Lacquer Wares" and (perhaps later) crude figurine incensarios. The new architectural forms persisted for the century and a half or two centuries until the Spanish conquest.

37.0. CHACCHOB

Chacchob, located north of the Puuc hills and 15 km southeast of the modern town of Teabo, has been known as a walled site since 1845, when an article on the site entitled “Una ciudad murada” was published by Fr. Estanislao Carrillo in Registro Yucateco. The site is relatively small, enclosed by a masonry wall measuring some 1,400 m in circumference. Monumental architecture is confined to a single complex and a few small structures, none of which is very elaborate. The site was probably occupied for a very short period of time within the Cehpech Ceramic Complex, 800–1000 AD. The site was surrounded by a masonry wall and was probably founded as a fortified community rather than later fortified. The site was the object of a three-day survey in 1952 by Harry Pollock and Stromsvik, and was later mapped, together with two other walled sites, Cuca and Dzonot Aké by David Webster during the winter of 1976–77.

37.1.

H.E.D. POLLOCK AND
GUSTAV STRÖMSVIK
Chacchob, Yucatán

YB 51:259–263, 1952

The ruins of Chacchob are in the District of Tekax, some 13 km by road and 10 or 11 km airline southeast of the town of Teabo. The site was first brought to the attention of the public over 100 years ago in an anonymous article that appeared in a Mérida periodical of the time. The part of the account that particularly has caught the attention of archaeologists is the statement that the ruins are surrounded by the remains of an ancient wall. Walled sites in the lowland Maya area are rare, and their occurrence is important because of certain implications as to the social structure and the general character of the civilization of the builders.

Although the information provided by the anonymous antiquarian of a century ago has from time to time been made use of by modern authors, the truth of his assertions, so far as is known to the present writers, had never been confirmed by competent archaeological opinion. The work of Carnegie Institution at Mayapán, the largest and most important walled city known in Yucatán, made it of peculiar importance not only to verify the existence of a possibly similar, nearby

site, but to know something of the character of the remains.

In May 1951, Eugenio May, a Yucatecan employee who has worked for many years with the Department, was commissioned to visit Chacchob and to report his observations, particularly with reference to any indications of a wall surrounding the ruins. May spent two days at the site, and his report left little doubt but that the ancient settlement had in fact been walled. It was consequently planned that further reconnaissance should take place during the 1952 field season.

Pollock and Strömsvik, traveling by truck, left the Institution's base camp at Telchaquillo February 27. The road, the old highway to Tekit, ran southeast through the ruins of Mayapán. Just short of Km 12, and approximately 10 km from the center of Mayapán, the site of Chumul was noted at the left of the road. This moderate-sized group of ruins, which was visited on our return journey, rests on a hill. The principal pyramid is clearly seen from Mayapán, and because of its natural elevation gives the impression at that distance of being a much larger structure than it is. This pyramid is flanked by lesser pyramidal structures, one on each side, and several mounds of indeterminate character complete the group. Although all buildings are fallen, the character of the masonry and the stone cutting, the architectural decoration, and certain monoliths mark the ruins as of the Puuc Period. Features observed include finely cut lintels and full-width jamb stones, colonnette façade elements, tapered columnar (*picote*) altars, and a rectangular altar.

Passing through Tekit (Km 21), a sizable town, our road continued south-southeast toward Chumayel and Teabo. At Km 25 we reached Hacienda Ukúm, where there are ruins and where May in the previous year had discovered a sculptured stone built into the floor of the abandoned machine house of the hacienda. This stone, which was photographed on our return trip, appears to have been a door jamb. It carries a rather typical Maya figure, erect and with plumed headdress, facing a vertical row of glyph blocks and standing above two horizontal rows of glyph blocks. The 13 or 14 hieroglyphs represented have not been deciphered. The sculpture and the character of the jamb stone suggest this to be a work of the Puuc Period, an impression strengthened by the presence of certain architectural elements (spools) typical of that period. A superficial view of the nearby ruins, disclosed them to be no more than mounds of stone, but better preserved structures may lie hidden in the forest.

Chumayel was passed at Km 34, and Teabo, a town of about the same size as Tekit, at Km 38. Teabo clearly was once an aboriginal settlement. A huge mound of rock, a large city block in area, from which much of the present town probably was built, gives ample testi-

mony to the size of the structure that has withstood four centuries of quarrying and still remains a massive bulk of stone. Across the street from this great pile are the ruins of a large and once beautiful convent of the colonial period.

Leaving Teabo, we continued southeast on the road that eventually reaches the village of Xaya. At Km 48 we reached Hacienda San Diego Max, once a henequen plantation, now turned over to cattle raising. The hacienda is the property of Jose Dolores Salas of Teabo, who most kindly offered us the use of his buildings, apologizing for their roofless condition. Here we made camp, our information being that this was as far as the truck could go. It was later discovered that with a small amount of clearing the road was passable as far as Chacchob. Our entire journey from Telchaquillo to San Diego Max consumed approximately 4 hours and 30 minutes (running time), of which 1 hour and 40 minutes were devoted to the 10 km from Teabo to San Diego Max. It was subsequently determined that the additional 3 km to the ruins was a trip of 20 minutes by truck.

Chacchob, now the site of a small cattle ranch, lies east-southeast of San Diego Max, on the road to Xaya. The ranch and the ruins are reported to be on the lands of the latter village. Previously this terrain was a part of Hacienda San Diego Max, and the corral walls, which include many stones, from the ruins, and the masonry curb of the well are unquestionably products of the period of hacienda ownership. This well is worthy of note. At first sight it appears to be of artificial construction, typical of the innumerable wells dug during the colonial period and in later times. On closer examination, however, it is apparent that only the curb and a small depth of fill below are man-made. The well proper is a natural bottle-shaped opening reaching down to water, in other words, a cenote. Deep rope cuts in the rim of natural rock below the artificial fill indicate centuries of use and almost surely date from the period of the ruins. This was the only source of water observed by us, or reported by the natives, within the area of the ruins. We did, however, hear of other natural water sources not far distant.

The ruins of Chacchob, which are surrounded by a wall, occupy a relatively small area covered for the most part by low, scrubby brush. Our explorations were confined rather closely to the territory within the wall, but there is no reason to believe that structures of any size lie beyond that limit, although house mounds may extend an indeterminate distance in any direction. The area outlined by the wall is a rough oval, some 500 m on the long axis, which runs east-southeast and west-northwest, and approximately 350 m on the shorter dimension. Passages through the wall were noted at the northeast, southeast, and southwest, with refer-

ence to the center of the oval, and what probably had been a passage was observed at the northwest

The ranch and well lie almost at the center of the ruins. Immediately to the north of center are two pyramidal structures, and a similar structure is just to the south. These range in height from possibly 6 m to 10 m, the highest being the northernmost. Farther south is a large, low rectangular platform, some 50 by 60 m, with a fallen, once vaulted building on the western edge. It is this building and the pyramid south of the ranch that have furnished much of the stone for the corrals and other post-conquest construction. In the eastern part of the site, approximately on the long axis, is the largest structure in the ruins, the so-called Castillo. An irregularly shaped platform that supported the remnants of once vaulted structures as well as house platforms occurs in the western part of the area. Remains of house platforms are scattered throughout the site, their number and concentration not being known.

Five days were devoted to exploration and study of the ruins. During that period data for a sketch map were gathered, architectural details were recorded, and a small amount of pottery was collected. No sculpture of consequence was noted.

The wall surrounding the site was a matter of primary interest. It differs from the wall of Mayapán in that it follows a course clearly selected to utilize, wherever possible, natural elevations of the terrain. This is strikingly apparent in the southeastern, southern, and western sections, where the wall follows natural ridges several meters in height for a distance that comprises something like two-thirds of the circumference. On the other hand, the Chacchob wall is very similar to that of Mayapán in design and construction. It consists of an inner bench and a higher, outer parapet, the whole built of rather large, roughly shaped stones. The parapet is for the most part formed of large stones set on edge, and generally does not rise more than 30 or 40 cm above the bench. Remains of a plaster floor on top of the bench at one point clearly indicate how that part was finished, and it is entirely possible, that all surfaces once were plastered.

The total thickness, of the wall would seem to average about 4 m. It is difficult to give any estimate of the present maximum height because of the confusion, without excavation, between what is natural and what is artificial. It would seem reasonable, however, to guess that the parapet attains at places a height of at least 2 m above ground. Maximum total height, including natural elevation, must be at least 6 m, probably more. Gates are simple cuts through the wall, the best preserved, those at the southeast and southwest, being about 2 m wide. Steps are visible leading up to these gates, this being made necessary by the natural rise.

The only structure sufficiently well preserved to offer any appreciable amount of architectural detail is the Castillo. This large complex of terraces and adjoining courts covers an area approximately 60 by 100 m. The principal and dominating building is a pyramid which rises in two great terraces to a height of 13–16 m above ground level, the difference in elevation being due to the natural slope of the terrain. No trace remains of the temple building that once must have crowned the pyramid. The structure faces west, as is shown by the stairway that rises from a courtyard at the foot of the pyramid. This courtyard is formed by ranges of vaulted rooms, some of which are still standing, that extend west from the northwest and southwest corners of the lower terrace of the pyramid. To the south of the pyramid and of the courtyard are other courts and terraces, some of which supported vaulted buildings now fallen.

There is good reason to believe that this large architectural complex grew by accretion. Construction may thus have extended over considerable time, and more than one cultural period may be represented. The fact nevertheless remains that all architectural details well enough preserved to form reliable criteria point to the Puuc Period. The vaulted rooms at the western foot of the pyramid are unquestionably of Puuc-style, and there are indications that the pyramid was built contemporaneously with these rooms, although this is by no means certain.

Nowhere else at the site was there noted standing masonry that would indicate the period of construction. There were, however, many examples of loose building stones which, by reason of design and style of workmanship could be associated with the Puuc Period. Only the wall around the site, because of its similarity to the wall of Mayapán, and a somewhat aberrant group of house platforms suggested any other period of occupation.

A number of structures that appeared to be the remains of dwellings were observed. These occurred both on platforms that supported the debris of vaulted buildings and on platforms with dwelling-type remains only. The characteristic plan is that of a rectangular room, or a series of two or three rectangular rooms, outlined by low stone walls, one or two courses high. Door-ways to rooms were frequently marked by jambs of larger stones. These low walls presumably were the foundations for houses of perishable materials. There also were instances of simple platforms which showed no surviving traces of houses but which might well have supported perishable construction. These house platforms occurred singly on a larger platform or terrace, or in groups of two or three that formed a small courtyard.

At no place was there noted the typical Mayapán type of dwelling with benches, nor was there noted an instance of a rear room [Chapter 1.40]. A group of houses with low walls that employed much cruder, stone work than all others seen suggested a different period of construction, but there was nothing to suggest a similarity to Mayapán. On the whole, the dwellings we observed approximate more closely the low walled remains, presumably domiciliary, that are found in the Puuc area.

During our last day at Chacchob time was available to dig one trench in search of pottery. This was located near a house platform. Soil was found to a depth of 40–50 cm before bedrock was encountered. Two arbitrary levels were maintained, each about 20 cm in depth. Only 165 fragments of pottery were recovered. R. E. Smith examined this material after our return to Telchaquillo. Thirty-six of the sherds were too eroded or too fragmentary to be identified; the remainder were typical of the Puuc Period. Nothing was noted that might be considered intrusive in Yucatán, nor was there a single sherd that might be suspected of belonging to the Mayapán Period. There were no significant differences in the pottery from the two levels in the trench.

We returned to Telchaquillo on March 4, having devoted five days to our reconnaissance of the ruins. The results of our work may quickly be summarized.

Chacchob is a small site surrounded by a wall. In many respects the wall is similar to that which encircles the ruins of Mayapán. On the other hand, the architecture of Chacchob, or such of it as was observed, both formal and domestic, seems to be of the Puuc Period. This time of occupation is further attested by the small sample of pottery recovered. As walled sites of the Maya lowlands are commonly considered to be of a period later than that of the Puuc, and roughly contemporaneous with the major occupation of Mayapán, these findings were unexpected. Interpretation of these observations, however, should proceed with caution. Our evidence is fragmentary, and there certainly remains the possibility that Chacchob underwent a late period of occupation, traces of which were not seen or not recognized by us. The wall around the site may represent that period, but in such case there should be other, contemporaneous remains. Before any conclusions are reached, it would be well to have a better knowledge of the house platforms and a much larger sample of the pottery.

38.0. CHICHÉN ITZÁ

Chichén Itzá is a largest Maya site in northern Yucatán with numerous buildings in various states of preservation. There is no above-ground water in the Yucatán peninsula, and the three natural sink holes (cenotes) providing plentiful water year round, made Chichén Itzá a natural spot for a settlement to develop. Two of these cenotes are still in existence, the most famous being the Cenote of Sacrifice (Cenote Sagrada), which was probably dedicated to the Maya rain god Chac. Offerings of jade, pottery, and incense have been recovered from the cenote, long a place of pilgrimage. Although Chichén Itzá was a major center by 600 AD, the city experienced its greatest growth and power after the collapse of the sites in the central lowlands to the south. Some of the notable Classic period structures at Chichén Itzá include a fine complex of buildings in the Puuc architectural style, known as Las Monjas (The Nunnery). To the east is La Iglesia, a small temple decorated with elaborate masks of the rain deity. To the north is the Caracol, a round building on a large square platform. This was an observatory with its doors aligned to view the vernal equinox. Apparently about 987 AD a Toltec king named Quetzalcoatl, arrived here

with an army from central Mexico, and made Chichén Itzá his capital, and a second Tula. The art and architecture from this period shows a blending of Maya and Toltec styles. The Temple of the Warriors at Chichén Itzá seems to have been built as a copy of Temple B at the Toltec capital of Tula. This is a stone building (originally with a wood and plaster roof) atop a stepped pyramid, with the columns in the interior carved with the likenesses of warriors. At the top of the stairway leading to the entrance of the temple is a type of altar-statue (chac mool). Dominating the center of Chichén Itzá is the Temple of Kukulcán, also referred to as El Castillo. This stepped pyramid with a ground plan of square terraces with stairways up each of the four sides to the temple on top. Great sculptures of Plumed Serpents run down the sides of the northern staircase, and are set off by shadows from the corner tiers on the spring and fall equinox. Seven ballcourts have been found at Chichén Itzá, one northwest of the Castillo is the largest ballcourt in ancient Mesoamerica. It measures 166 m by 68 m. The interior sides of the ballcourt are lined with sculpted panels depicting ball players. Built into one of the exterior walls of the ballcourt is the Temple of

the Jaguar, which features a jaguar throne. Chichén Itzá also has a variety of other structures densely packed in the ceremonial center of about 5 sq km and several peripheral sites. The Maya chronicles record that in 1221 a revolt and civil war broke out, and archeological evidence confirms that the wooden roofs of the great market and the Temple of the Warriors were burned at about this date. Chichén Itzá went into decline as rulership over Yucatán shifted to Mayapán. While the site was never completely abandoned, the population diminished and no major new constructions were built. The Sacred Cenote, however, remained a place of pilgrimage. In 1531 Francisco de Montejo claimed Chichén Itzá and intended to make it the capital of Spanish Yucatán. After a few months an indigenous insurrection drove off Montejo and his forces.

Modern investigations at Chichén Itzá began in 1838 which Benjamin Norman, followed by John Lloyd Stephens, published accounts of their visits to the ruins of Chichén Itzá. About 1890 the United States Consul to Yucatán, Edward H. Thompson bought Chichén Itzá and spent some 30 years exploring the ruins and dredging artifacts from the Sacred Cenote. In 1924 the CIW began a 20 year excavation and restoration project, which included restoring many of the buildings at the site. In 1961 the Sacred Cenote was again dredged, but more thoroughly by Mexico's Instituto Nacional de Antropología e Historia (INAH). In the 1980s INAH excavated and restored some additional buildings. Chichén Itzá is today a World Heritage Site and a very popular tourist destination. It is the most visited of the major Maya archaeological sites.

38.1.

EARL H. MORRIS

Report on the Excavations at Chichén Itzá, Mexico

YB 23:211–213, 1924

On May 27, after one week's preliminary work, consisting of cutting new growth and burning the vast mass of timber felled in 1923, excavations were begun in the Court of the Thousand Columns at Chichén Itzá. The first point attacked was the natural entrance to the Column Group walking westward from the Castillo, a passageway through the building which flanks the western side of its main plaza. The building, which it transects faced the west and consisted of a thick back wall, paralleled by four rows of rounded

columns, the fallen drums of which were scattered over the area excavated. The passage itself was about 6 feet [1.8 m] wide. It had been roofed with a typical Maya vault where it passed through the back wall, but had not been covered thence eastward.

Leading through the terrace, which supported the building along the north side of the main plaza, was a partially choked tunnel, only the extreme ends of which had fallen. This was the next feature excavated. It proved to be 66 feet [20.1 m] long, 4 feet 9 inches [1.5 m] wide at the bottom and 6 feet 5 inches [1.9 m] from floor to capstone. The exposed faces of the terminal stones of the arch, both at the north and the south ends of the tunnel, had been elaborately sculptured motifs being jaguars and macaws.

The principal excavations of the season were centered upon the extreme northeast corner of the Column Group. The structure cleared there. Has been designated the Northeast Colonnades. It is an edifice 100 feet [30.5 m] in length by 49 feet [14.9 m] in width, facing south. The east, north, west, and the ends of the south boundaries were solid walls, but the remainder of the support of the super structure was a series of columns, rectangular in cross-section. These are distributed in five rows from east to west, the northern four being 10 columns in length; the south, which is in reality the interrupted south wall, having only 8. These 48 columns vary little from 2 feet 4 inches [71 cm] from north to south and 2 feet [60.9 cm] in opposite direction, and are separated by an average distance of 7 feet 2 inches [2.2 m]. Their original height was practically 8 feet [2.4 m] above floor-level.

The columns being rectangular, there was no necessity for capitals. Only the fifth and sixth columns of the two back tiers were sculptured. Graven into each face is the figure of a warrior in full regalia. Inclosing the two sculptured columns of the northernmost tier is an altar or throne extending thence to the rear wall of the building; it is 13 feet 3 inches [4 m] east and west, 7 feet 3 inches [2.2 m] north and south, by 3 feet [91.4 cm] high. The walls consist of a battered lower zone surmounted by a vertical cornice. Both of these elements were elaborately sculptured, the former with figures of warriors, the latter with intertwined serpents, from the mouths of which issue other warriors.

Bordering the east, north, and west walls is a broad bench, upon the rear edge of which is a row of stone slabs, their tops leaning against the walls, thus providing a sloping surface with an angle which would have afforded a convenient back rest for any one reclining upon the bench.

The arches of the building run parallel to the longer dimension, that is, east and west. These had rested upon pairs of hewn timbers which spanned the space from wall to column, or from column to column as the

case might be. At the western end, where preservation was best, the proportions of the beams and every detail of arch construction were recovered. It was possible to ascertain that 106 beams had been used in the roof construction.

The hard, polished lime floor and the entire interior of the building had been painted, a rich deep red being the dominant tone. The bounding walls had been embellished with designs, composed, in the one place where the elements could be distinguished, of serpents and feathers done in yellow, blue, green, and red.

There was ample evidence of secondary construction. A rectangular room had been cut out of the northeast corner of the great hall by walling-in the spaces between columns, and extending from the altar westward, all intervals between the columns of the second tier from the north had been filled with dry-laid walls, probably for the purpose of holding up timbers which had begun to fall. Reused sculptured stones were plentiful in the secondary masonry, many in the northeast room evidently having come from the front façade, and several in the dry-laid wall having been torn out of the face of the altar.

The north side of the building, which rests upon a high embankment heaped up upon the sloping margin of a dead cenote, had begun to fall previous to abandonment. In an effort to strengthen the first column in the back row westward of the altar, a wedge of masonry had been built between the column and the rear wall. Forming the bulk of this were five Atlantean figures, and a sixth was found in one of the intercolumnar secondary walls.

The principal units of the façade, were a battered basal zone, a vertical medial one, and a sculptured upper zone. At the west end of the south wall, owing to the fact that this part had been buried by the hearting of a stairway built subsequently against it to give access to a higher temple to the westward, the entire sculptured zone, though riven by settling and the roots of trees, was in place, thus revealing the nature and arrangement of some of the motifs. The lower cornice was composed of three members, of which the central band consisted of intertwined serpents with disks between the coils. At the western terminus the grotesque head of one of the serpents stood out in high relief, and beside it was a block, graven to represent the rattles of the tail of the serpent which extended in the opposite direction. Filling the vertical expanse above the serpent's head were two grotesque masks, one above the other. Surmounting these was an upper cornice, a repetition of the lower zone, except that the stones of its upper member were elongated, their tips forming the edge of the roof. Eastward from the mask panel, and separated from it by a plain band, was a vertical panel consisting of three disks or shields in relief.

Masks and shield panels, alternating with grotesque human figures, continued thence to the southeast corner of the building where the arrangement was the same as previously described at the western end, except that the line bisecting the 90 degree angle formed by the corner would have been the medial line both of serpent's heads and masks. The western end of this façade was taken down and reset in cement, and the lower cornice replaced from fallen elements at the eastern end. The series of terraces leading from the north side of the structure down to the floor of the adjacent dead cenote will be cleared of débris and repaired next year.

The western terminus of the Northeast Colonnade abuts a much higher mound, on the south end of which there had been a small one-roomed structure of which only the basal courses remained. The platform on which it stood was composed of rough stones, filling and heaped up against and around an earlier edifice extending at right angles to the Northeast Colonnade. Whether it was pre-existent or contemporaneous has not as yet been determined. The southern end of this partly buried temple was excavated. Being the portion which was not filled up to form a base for the elevated one-roomed temple, and, therefore available for subsequent use, it had been remodeled to form an individual structure, facing east, of essentially the same form as the Northeast Colonnade. The columns here are round, but surmounted by rectangular capitals. There are two doorways and one row of columns between them and the rear wall. A wide bench flanks the south and west walls. Extending forward from this to, and somewhat beyond the central pair of columns, is a platform analogous to the one in the Northeast Colonnade. Throughout the building is of relatively poor construction. Extending into the mound at the northern limit of excavations, a portion of the sculptured façade is in place, revealing a large disk or shield as one of its elements.

The two buildings cleared seem to confirm the type of the most prevalent form of column-supported structure at Chichén Itzá, the features of which are a rectangular ground-plan with arches paralleling the longer dimension, a bench contiguous to the end and back walls, and an altar or throne at the center in the rear.

As might be expected in this class of excavation, the minor objects recovered were few; a fair quantity of potsherds, two nearly complete vessels, a few shell beads, a jade celt, and several flaked blades of obsidian.

With the completion of the replacement of the façade at the southwest corner of the Northeast Colonnade, the field work for 1924 was brought to a close on July 12.

38.2.

J. O. KILMARTIN

*Report on the Survey and Base-Map at
Chichén Itzá, Mexico*

YB 23:213–217, 1924

In accordance with arrangements made by the Carnegie Institution of Washington and the United States Geological Survey, I proceeded from Washington on November 21 and sailed from New York on November 24 to Yucatán, Mexico, to undertake surveys of various natures for the Carnegie Institution at the ruins of Chichén Itzá, arriving at the port of Progreso on November 30 and at Mérida a few hours later.

After presenting my credentials and letters of introduction to the governor of Yucatán, the late Don Felipe Carrillo, and to Don Felipe Cantón, president of the Archaeological Society of Yucatán, both of whom assisted greatly in facilitating my arrangements for supplies and transportation to Chichén Itzá, I proceeded to that place on December 5 and began immediately to take up with Mr. E. H. Thompson, the owner of the hacienda of Chichén, the proper location of the 100 acre [0.41 square kilometer] tract provided for in the lease arranged by Dr. S. G. Morley several months earlier.

This having been completed, the next work undertaken, according to instructions, was the collection of building stone, palm leaves for thatching, and poles for the new house to be built in front of the Casa Principal as well as for the laborers' houses to be built to the south of the Park Chichén, and also a preliminary survey and study of the Group of the Thousand Columns.

A scale of 50 feet [15.2 m] to one inch was selected for the map of the Columns, and this work was completed the latter part of January.

The principal work at Chichén Itzá during the 1924 field season was the topographic map of the site, which covers nearly a square-mile [2.6 sq km].

After several days of close inspection of the ruins in the Federal Archaeological Zone, as well as those surrounding the Castillo for perhaps three quarters of a mile [1.2 km] on each side, an area was selected with the Castillo as the center; the border lines to extend as far there from as was deemed necessary.

It was found from the survey of the Group of the Thousand Columns, which was made on a scale of 50 feet [15.2 m] to an inch, that a scale would have to be adopted that would show clearly a distance of from 4 to 8 feet [1.2–2.4 m], 4 feet [1.2 m] being the average width of walls of buildings and 8 feet [2.4 m] being the average distance of columns from center to center.

Measurements taken on approximately 500 columns showed that they averaged 1.91 feet [58 cm] in diameter, while measurements on about 100 capitals gave an average of 1.70 [52 cm] by 2.12 [64 cm], and it was also found by a like number of measurements of distances between columns that they were not equally spaced, ranging anywhere from 7.7 to 9.9 feet [2.4–3 m] in distance apart (center to center). According to the above figures, a scale of 1:2,400 or 200 feet [61 m] to 1 inch was selected. This later proved to be very satisfactory, for sufficient detail could be shown on each building so that it could be readily identified.

The next question of importance was the selection of a suitable contour interval. After taking several measurements of slopes and depressions and plotting these to scale, it was found that a contour interval of 5 feet [1.5 m] would depict the country with sufficient accuracy for all purposes.

The above details having been decided, a point on the lowest step inside of the south balustrade of the west stairway of the Castillo (the best preserved of all) was selected as the starting point, and this was later tied into a position established on the platform of the Castillo by the Geodetic Commission of Mexico, in a scheme of triangulation extended over the peninsula in 1918. This position is 5 feet [1.5 m] north of the west column in the entrance to the outer chamber of the Castillo, and is in latitude 20 degrees 41' 01.324" north and longitude 88 degrees 34' 09.444" west, and all projection lines are based upon it.

Positions of the points marking the corners of the Federal Archaeological Zone were obtained from the Comisión Fomento and were plotted on the map to be used as control. These positions did not agree with plane-table positions in each instance, so an adjustment was made to take care of these errors.

The first line of traverse extended from the selected position on the lowest step of the west stairway of the Castillo, which was also used as the datum plane to which all contours and elevations are referred, along the roadway to the Hacienda Chichén, thence turning west and north following the trail past the Monjas and back to the point of beginning. The closure error on this line was very satisfactory and did not require adjustments. Distances were read to the nearest foot [31 cm] and elevations to the nearest tenth with a Gurley alidade and stadia rod graduated to hundredths of a foot.

With the completion of this circuit, a point in front of the Caracol and on the trail was used as a starting point and a line carried west to the border of the map, approximately 2,400 feet [732 m], and at intervals of 200 feet [61 m] lines were cut north and south to the north and south borders. This method was repeated over the entire area which was gridironed into 200

foot [61 m] squares. Plane-table stations were established at alternate intersections, and elevations were established midway of all lines and at angles to the center of squares enclosed by lines from this and other stations. It will be seen by the foregoing that every 1,600 square feet [148.6 square m] was controlled by 13 elevations. To get these elevations it was necessary to cut lines that totaled approximately 40 miles [64.4 km] in length through the brush, which at times was so dense that it was possible to cut only half a mile [0.8 km] a day with the aid of eight men.

During the course of the survey it was found necessary to extend the borders of the map in each direction on account of new ruins discovered, which conflicted with the border line as selected with the Castillo as a base. This procedure, however, had to be abandoned when it was found that the borders could be extended indefinitely in each direction and still take in a ruin of some kind. The numerous ruins found during the survey were, to no little extent, covered with a heavy accumulation of debris and vegetation which rendered it very difficult to trace out their lines of construction.

In many instances the Maya seem to have selected a hillside and built to the level of the top, rather than construct an entirely artificial terrace. This was very confusing, for it made the tracing and location of contour lines difficult and indefinite.

The first carved stone found was that of a figure, presumably of a deity, in a sitting position, in the bottom of the dry cenote just to the west of the Monjas. This figure was almost completely buried in the sediment of the cenote and was either carved *in situ* or close by, or else it had tumbled from the ruin just above to the west.

The next stone was of the Chacmool type and was found just south of this cenote and west of a very much destroyed ruin about 200 feet away.

The third stone found was the head of a snake in the process of being carved out, in a small artificial depression or quarry about 800 feet to the west of the south end of the Ball Court. This sculpture is of importance because it shows clearly the process of carving stone in the immediate vicinity where found. Judging from its location it would appear that the Maya obtained the major portion of their stone from ledges which had been broken up by natural processes, that is, by the breakage of the roofs of subterranean chambers and the exposure of a mass of dissected rock which was later fashioned into various shapes for building purposes.

The next stones of importance were two which had been carved into snake tails and shaped in a right-angular form; these were found about 400 feet east of the slight angle in the road before entering the gates of

the *planta* at the schoolhouse. The location of these stones would suggest that a building was in the process of construction somewhere, but there was no evidence of construction lines on this terrace.

Close by these stones, and a few hundred feet to the north, is found a tiger carved in deep relief on a rock ledge. There is no evidence of further cutting with the intention of removing this stone elsewhere.

The next, which conclude the list of important stones found, were those just east of the Federal Monument on the trail that leads to the Cenote of Sacrifices, on the Great Terrace. These stones are of a very heavy relief and show extensive use of feather decorations. There is no building close by that might suggest their provenance.

The most important group of ruins found outside of the Archaeological Zone is that which has been designated the Northwest Group located north and west of the Great Ball Court. This group is remarkable for its deep and well-preserved carvings.

In the center of this group was found a small mound about 4 feet [1.2 m] high, which resembles closely the tombs found directly in front of the Osario. With Mr. E. H. Morris, I trenched into the center of this mound to a depth of about 5 feet [1.5 m] and discovered that it was not a tomb but presumably a sacrificial altar. The numerous mounds, temples, terraces, altars, and various other structures at this group are so extensive that they can not be described here, but will have to be covered in subsequent reports.

Measurements of the Great Terrace show that it contains an area of 47 acres [0.2 sq km] and had been built up in some places to a height of 25 feet [7.6 m]. On this terrace are located the major buildings, the Castillo, the Great Ball Court, and the Group of the Thousand Columns; and the lesser buildings, the House of the Eagles, the Tomb of the Chacmool, and a nameless structure.

Foremost among the interesting facts discovered in this group of buildings may be said to be the acoustic properties of the Great Ball Court. Tests made with the human voice, as well as with a small phonograph located in the North Temple, showed that the voice carried remarkably clear to the South Temple, 500 feet away, when a person was talking in a natural tone.

In a slight break in the south wall of the principal pyramid of the Group of the Thousand Columns, were revealed mural paintings of a dark red and yellow. This building is completely covered with debris and vegetation, and excavations here might reveal paintings and sculptures remarkably well preserved.

Numerous paved roads were traced leading away from the Great Terrace and in each case they appear to have been covered with plaster and flanked on both sides by low walls perhaps 2 feet [61 cm] wide.

Upon the completion of field work and after pointing out to Dr. Morley numerous features observed at Chichén Itzá and going over the area mapped, I left Yucatán on June 10, arriving in Washington on June 17. After a short leave of absence I returned to Washington to complete office work on the maps which were turned over to the Institution on July 24 ready for engraving.

Thanks are due to the many persons who assisted in various ways in all this work, and especially to Mr. W. M. James, of Mérida, and Mr. O. Gaylord Marsh, American Consul at Progreso, who so kindly extended their services whenever needed. Thanks should also be expressed to the United States Geological Survey for its cooperation in this work and the numerous facilities, which it has extended.

38.3.

EARL H. MORRIS

*Report on the Temple of the Warriors
(Station 4)*

YB 24:252–259, 1925

The pyramid temple upon which excavations were centered during the season of 1925 is situated contiguous to and northward of the northwest corner of the Court of the Columns. This structure, which had not been cleared of forest since Maudslay's visit in 1889, had remained the largest edifice in the city untouched by the hand of modern man. When the undergrowth had been removed, it was seen that the pyramid and the temple surmounting it had been reduced by time and the elements to a square-cornered hill, 50 feet [15.2 m] in height, differing in appearance from a natural one chiefly because of the profusion of faced and sculptured stone strewn down its slopes.

In common with the other structures composing the Group of the Thousand Columns this pyramid rests upon the vast artificial terrace upon which the Castillo, the Ball Court, and in fact most of the Toltec-Maya portion of the city was built. The talus of debris, fallen from the temple above, rose from this major terrace level across the entire eastern side of the pyramid and along the eastern end of the north side as well. Toward the western end of the northern exposure the debris encroached upon detritus from the Temple of the Tables, filling the passage between the pyramid and the substructure of the latter to a depth of as much

as 8 feet [2.4 m]. Along the south side of the pyramid there is a V-shaped gully, draining to the east, through which one may ascend from the major terrace to the surface of the mound covering the western end of the north range of the Group of the Thousand Columns, which passes in front, that is, west, of the pyramid. This latter is a long and relatively low mound formed by the collapse of a rectangular building with its longer axis running north and south, and which faced west. A wide rib of hearting with a more gradual slope than the debris on either side of it, its base buried beneath a mass of fallen step elements, indicated that the stairway to the temple above, ascending the western face of the pyramid, had risen through this long low structure.

Before excavation the summit of the pyramid was a series of hummocks and depressions with here and there a rectangular block of stone, apparently *in situ*, protruding from the surface, the arrangement of these indicating that the rows of columns had run from north to south. Among the detached, elements, arch stones and fragments of roof ornaments were conspicuous. On the proportionately broad western terrace, the two large tail pieces of the serpent columns at the entrance, as well as rectangular elements of the once vertical bodies, lay as they had fallen from the façade, while a battered Chac Mool figure lay midway between them. Except the latter, which had been partly turned around in an attempt to remove it to Mérida, these stones lay as shown in Maudslay's illustration of Mound 18 (Maudslay 1889–1902:3: Plate 63).

The work of excavation was begun late in February, and continued until the closing days of June. The crew of workmen varied in number from 15 to 50, and in addition, during the latter part of the season, seven masons and their assistants were placed upon the repair work, and these together with burners of lime and diggers of white earth to mix therewith augmented the force to a maximum of 85.

The Temple of the Warriors, as the structure on the summit of this pyramid has been styled, was completely excavated by the end of June. All of the debris on the northern and southern sides of the pyramid had been removed, and a bulk equivalent to the mass which had been cleared out of the temple and dumped down the eastern slope had been carted away. In addition a drift, the width of the stairway, had been out through the low building at the western foot of the pyramid, and a passage had been made between the northern end of the structure thus transected and the southwest, corner of the substructure of the Temple of the Tables.

With one exception all fallen columns in the area excavated, were set-up again. The repair of those portions of the temple-walls which could be replaced in

their original positions with absolute certainty was approximately, half completed, and about one-fourth of the facing of the pyramid had been reset before the beginning of the rainy season put an end to the work.

Although its symmetry is marred by the addition of the structure lying west of it, for purposes of description the pyramid crowned by the Temple of the Warriors may be considered as a block of masonry 133 feet [40.5 m] square, and between 36 and 37 feet [11–11.3 m] in height. The basal element is a platform, varying from a few inches up to a foot and a half [46 cm] in height, evidently erected for the purpose of providing a foundation more nearly level than irregular surface of the major terrace. The battered face of this foundation, which has been found *in situ* along the north, east, and one-half of the south sides of the pyramid, is composed sometimes of one and sometime of two courses of stone. The narrow terrace, or walk, bordering the true foot of the pyramid averages slightly more than 3 feet [91 cm] in width. From this level upward, the face of the pyramid was symmetrically divided into four multiple zones or platforms, a general description of one of which will, with slight variations dimensions, suffice for them all.

The lowest element is a battered wall 5 feet 6 inches [1.7 m] in height rising with a gradient of 65 degrees to 75 degrees from the horizontal. The corner stones are excellently hewn slender blocks tapering from base to tip. The stretch of wall between them consists of four courses of smoothly faced blocks, varying in height, and very closely joined.

Surmounting this battered wall is a vertical 6 inch [15 cm] cornice, composed of a single course projecting from 6 to 7.5 inches [15–19 cm]. Set back 2 inches [5 mm] from the upper margin of this is a two course vertical band 2 feet 3 inches [68 cm] in height, elaborately sculptured. The terminal blocks of this band, composed of single stones, are recessed, their corners being flush with the cornices above and below them, and their recessed portions flush with the carved band. Above the latter is a second 6 inch [15 cm] cornice like the one beneath, projecting the same distance. From the brink of the upper cornice to the foot of the multiple zone there is a very slightly sloping terrace, 3 feet 2 inches [96 cm] in width.

Decorative elements appearing in the sculptured bands are pairs of semi-reclining male human figures, feet to feet, elaborately clad, each bearing a long plumed staff, these pairs being separated by two squatting creatures sitting either face to face or back to back. The jaguar and the eagle are plainly identifiable in these non-human pairs, but the identity of the third figure; a chunky, thick-haired, stubby-tailed quadruped has not yet been determined. Usually a speech-scroll issues from the mouth of the man, beast, or bird as the case

may be, and various other scrolls appear around the figures.

Portions of all elements of the face of the pyramid were found *in situ* up to, and including, the lower cornice of the fourth multiple zone. Inasmuch as the distance thence to the top of the pyramid is just sufficient to allow for a finishing vertical band and its overlying cornice, it may be justifiably inferred that the arrangement of the fourth multiple zone was essentially the same as that of the lower three. However, it is still an open question whether its vertical band was sculptured or not. At present it would rather appear that it had been plain.

From the brink of the fourth multiple zone, the summit of the pyramid extends back, with a gradient sufficient to provide good drainage, to the foot of the temple. The original widths of the three platforms on the north, south, and east sides have not been calculated as yet, but the western platform, that is, the one in front of the temple, is 25 feet 10 inches [7.9 m] wide.

The hearting of the pyramid is of masonry throughout. This great mass was raised a course at a time. Over the previous course a layer of stone was spread, the interstices were filled with smaller stones, and then lime mortar was laid over the area, troweled smooth, and allowed to set before the next layer was put down. Thus the individual courses rest upon a smooth surface, but are not bedded in mortar.

Much of the building material was reused from older structures. Practically every type of structural element has been found built into the core of the pyramid, such as faced blocks from vertical walls, cornice blocks, arch stones, and sculptured elements, both in relief and in full round.

An indeterminate number of earlier structures once occupied at least portions of the area of the pyramid. Two have been identified, one at the southwest corner, the other at the northwest corner. The roof edge of the former was found at the level of the terrace surmounting the second multiple zone. A pit sunk to a depth of 15 feet 6 inches [4.7 m] in the southwestern corner at this point revealed a complete façade of a Toltec Maya building, viz., battered basal zone, battered cornice, vertical zone, vertical cornice, vertical zone, vertical cornice and roof margin. The temporal relationship of this structure and the pyramid will be considered at another point.

The second partially enclosed, partially dismantled building is revealed by a floor level and a standing column in the northwest corner of the pyramid. This floor level is approximately halfway up the pyramid, and the warriors carved on the sides of the column face west, proving that whatever was the area covered by this building its front was toward the west.

The Temple of the Warriors proper is approximately 69 feet square [6.4 m square], with its only entrance facing west. A cross-section of the outer face of the wall reveals a battered lower zone 5 feet [1.5 m] in height, rising at an angle of 77 degrees, an 8 inch [20 cm] battered cornice receding at an angle of 63 degrees, a vertical zone 6 feet 6 inches [1.9 m] in height and an 8 inch [20 cm] vertical cornice. The remainder of the elevation may in the end be calculated with reasonable accuracy, but as no portion of the upper walls remains *in situ*, a restoration would be more or less hypothetical. The elements wanting to complete a typical Toltec-Maya façade would be a vertical zone, a vertical cornice, and a roof margin. Thus while the treatment of the outer walls to the height of the doorway is established beyond doubt, the part above this is as yet undetermined. The battered basal zone and battered lower cornice are unsculptured. The carving upon the remaining vertical band on the north, south, and east sides described as one: a pair of duplicate, grotesque masks, one above the other the medial line, forming the apex of the angle, occupies each of the four corners. Midway between them, that is, at the center of each wall, there was another pair of masks, like the terminal ones, except that they are on a flat between the bird-like claws, and within the widely gaping jaws of the serpent appears a human head carved in half round.

The entrance to the temple is gained through a triple doorway, 25 feet 8 inches [7.8 m] in width, the division into three being accomplished by two magnificent serpent-columns, the bases of which were found *in situ* and the other elements fallen in such alignment that they could be reassembled with no possibility of error. Against either jamb is a false column or pilaster, 1 foot [31 cm] thick and 1 foot 5 inches [0.4 cm] wide, with the figure of a warrior carved on each exposed face. The sides of the jambs protruding beyond the pilasters were also sculptured.

The horned serpents' heads with opened jaws, most skillfully carved, are about 4 feet 7 inches [1.4 m] long and lie flat upon the terrace; rising behind them are the rectangular bodies, each composed of seven blocks with horizontal, dimensions of 2 feet 2 inches [66 cm] by 2 feet 4 inches [71 cm], and each embellished with incised scales and flowing plumes. Surmounting each body is a tail piece projecting forward, not quite so far as the head; with upward flung, handsomely graven rattles terminating in a tuft of plumes. The wooden lintels of the triple doorway rested on these columns at a height of 12 feet 2 inches [3.7 m] above the floor, but the plumed tips reach upward an additional 3 feet [91 cm]. The existence of the wooden lintels, which once capped the doorways, is known from inference only, since all three of them had been completely destroyed.

Figure 38.3.1. Chichén Itzá, Temple of the Warriors, plan.

Beyond the portal lies the outer chamber, a hall 61 feet [18.6 m] north and south by 29 feet 2 inches [8.9 m] east and west. Dividing it longitudinally are two rows of six columns each, symmetrically placed, each column 12 feet 2 inches [3.7 m] in height. The roof had been in the form of three vaults running from north to south, and had rested upon wooden lintels connecting these columns. These wooden lintels had been 8 inches [20 cm] in thickness. The plaster marks on the capstones show a width of slightly more than one foot [31 cm] for the arch cap. Detached stones suggest that there had been a vertically faced course 4 inches [10 cm] in height, immediately below the cap stones. The height of the arch will eventually be learned from a study of the trapeziform stones, which formed the exposed surface where the arch was inserted in the end walls of the room. All that can be stated now is that the vaults were very high, as shown by the fact that the material in the roof was sufficient to fill the temple to the average height of the columns, or 12 feet [3.6 m] plus.

In the center of the back or eastern wall of the outer hall a doorway 10 feet [3.1 m] wide gives access to the inner chamber. This door was 7 feet 11 inches [2.4 m] high, and its functional width was reduced to the same dimension by a false column or pilaster against each jamb. Both pilasters and jambs are sculptured on the three exposed surfaces like those of the main portal.

The inner chamber has practically the same dimensions as the outer one. Four rows of two columns each cross it from east to west. The roof, which these supported, had consisted of five vaults running east and west, that is, at right angles to those in the outer chamber, the central one having a span of 13 feet 9 inches [4.2 m], the other four a span of 9 feet 9 inches [2.97 m]. A bench 5 feet 7 inches [1.7 m] wide and 2 feet 10.5 inches [87 cm] high, with a marginal cornice 6 inches [15 cm] in height projecting 3.5 inches [8.9 cm],

flanks both end walls of the room, and turns to follow the east wall, north or south as the case may be, for a distance of 7 feet 7 inches [2.3 m].

At the extreme back of the temple occupying the space between the east wall and the eastern pair of columns which support the extraordinarily wide central arch, there is a beautiful altar 14 feet [4.3 m] in length, 7 feet 10 inches [2.4 m] in width, and 2 feet 8 inches [81 cm] high. The top surface or floor is composed of three rows of slabs paralleling the wall, five each in the front and center rows, and eight in the back. These are supported by 19 Atlantean figures and eight conical stone posts placed tips downward, each having a square capital like the typical round columns of this group. Many of the elements of the altar had been reused. Several of the Atlantean figures, for example, were too tall for the height of the altar, and in consequence their feet were let down into the floor. In such cases, other feet replacing the buried feet were modeled of lime mortar to convey the impression that the figures stood on the plane of the floor. This treatment was also applied to some of the stone posts. Moreover some of the finely worked floor-slabs in the center and front rows evidently had been torn out of previously existing altars since the interlaced serpents carved upon their edges were found not only upon exposed surfaces, but also upon inside surfaces which were hidden by other of the floor-slabs.

The columns in both chambers are elaborately sculptured. The face of each column shows the same general plan of treatment: a priest or warrior standing above a panel carved to represent a heteromorphic head which also occurs between the marks on the exterior walls of the temple as already noted. Above each figure is a second panel constituting a distinct decorative element. The columns were painted in brilliant colors, and in fact the entire interior of the building, floor, walls, and roof, was finished in colors. The smooth, highly polished lime floor was painted a rich dark red. Subject to slight local variation, a dado 5 feet 6 inches [1.7 m] high encircled the bases of the interior walls. Beginning at the floor level, and going upward, there is a 3 foot 6 inch [1.1 m] band of red, a 5 inch [13 cm] one of blue, a 6 inch [15 cm] one of red, a 5 inch [13 cm] one of yellow, and a 7 inch [18 cm] top one of black. Continuing thence upward to and including the roof cap, were depicted a great variety of subjects: men, animals, birds, serpents, fish, plants, and marine scenes. Since the best preserved paintings are now to be found on the fallen stones, the relationship and arrangement of the individual subjects can not easily be determined.

Painted embellishment was not confined to the interior alone, however. All sculptured stones which had been sufficiently protected from weathering for

color to remain upon them, whether from the temple proper or from the pyramid, showed traces of red, blue, and green. The battered basal zone of the temple exterior retained plaster in places to a depth of 2 inches [5 cm], consisting of upwards of 100 coats. Nearly every coat bears daubs and splashes of pigment which dripped from the brushes of the painters at work on higher sections of the walls. One coat deeply buried by subsequent applications of white lime plaster, was covered with bold, rather carelessly drawn murals in red, yellow, white, black, and green. The parts of this which have been laid bare depict male human figures bearing long staffs like those in the hands of the reclining men in the sculptured bands on the sides of the pyramid below.

In the light cast by partial excavation, the structure at the western the pyramid, or as it has been called the Northwest Colonnade, is a building approximately 150 feet [45.7 m] in length and 45 feet [13.7 m] in width, facing west. It contains four rows of rectangular columns running from north to south, the three eastern rows having 16 columns each, and the western one only 14 columns, because the positions of the terminal columns in this latter case are occupied by the antae of the front wall.

Standing in front of the Northwest Colonnade the following arrangement is revealed: first three steps leading from the general level of the major terrace to the frontal platform 12 feet 3 inches [3.7 m] in width which supports the Northwest Colonnade. The temple stairway is as wide as three intercolumnar spaces of the Northwest Colonnade. In line with each of the two included columns, a balustrade leads over the steps from the major terrace level to the frontal platform. Built out from the riser of the upper step is a block of masonry, and tenoned into it, and projecting out over the balustrade, is a serpent's head. The northern one of these was found *in situ*, but the southern one is missing.

Counting inward from the frontal platform, the temple stairway begins just behind the base of the third row of columns. Since the Northwest Colonnade is four intercolumnar spaces in depth, it is seen that the base of the stairway extends out halfway into the lower hall. Occupying the positions of the two columns of the inner tier, which normally would have risen from that part of the floor now occupied by the base of this stairway, there are two columns rising from the stairway, their bases being on a level with the tops of the other columns in the same row, both to the north and south of them. Across the stairway the fourth or inner vault of the Northwest Colonnade was omitted, and the eastern half of the third vault as well. The western side of this third vault was continued upward fully twice its natural distance until it reached and was supported by the two elevated columns rising from

the stairway. Thus the approach to the Temple of the Warriors lay through the Northwest Colonnade, and the base of the stairway, which lay within the confines, of this lower hall, rose beneath an inclined roof.

The stairway is flanked by broad low balustrades which were interrupted in their central parts by the vertical walls forming the ends of the intersected inner vault of the colonnade. The parts of the balustrades below this wall are in place and are carved in low relief with representations of the rattles and sinuous body of the plumed serpent. That portion of the balustrades, which would have been above the roof of the colonnade is now fallen. Two very large serpent heads found on the surface, one at each side of the stairway, however, presumably were tenoned in the tops of these balustrades, projecting over them just as in the case of the smaller ones in the balustrades in front of the lower hall.

The first 10 steps of the stairway had been deeply buried, and were perfectly preserved. The individual steps presented little variation from a riser and tread of 10 inches [25 cm] each. The stones were so skillfully cut and joined that this stairway ranks as the most excellent in point of construction yet found at Chichén Itzá. As many as 26 coats of lime plaster had been applied over the steps, some of them having been painted red. In the debris covering the base of the stairway were found a fang and three horns belonging to the heads of the serpent columns of the Temple of the Warriors and two human statues carved from stone, all cast down from above in comparatively ancient times, doubtless by the hand of man.

The Northwest Colonnade encroaches upon the western slope of the pyramid to the extent that the two lower multiple zones of the latter do not occur at all, the outer face of the colonnade wall rising from the terrace at the top of the second multiple zone a yard [91 cm] distant from the foot of the third.

Here arises the question as to the age of the façade found buried in the southwestern corner of the pyramid. Obviously this façade belongs to an earlier structure, and in preparation for the erection of the pyramid, all of it, even to the inner facing of the wall in question, was torn down. Presumably the Northwest Colonnade is secondary to the pyramid. In conformity with this assumption, the two lower zones of the pyramid once continued to the general level of the major terrace on its western side, and were eventually torn out to allow for the construction of the back wall of the Northwest Colonnade.

So far there has been found little to indicate whether the Temple of the Warriors was erected previous to, contemporaneous with, or later than the range on the north side of the Court of the Columns, the western end of which lies immediately south of the pyramid. However, the extreme western end of this range is

composed of certain units, some of which, if not later modifications of the original structure, at least show that they are secondary to the pyramid.

Excavations in the gully mentioned as occurring parallel to the south side of the pyramid disclosed a passage, its floor at the level of the major terrace, continuing westward 48 feet 5 inches [14.8 m] from the southeast corner of the pyramid. The southern boundary of this passage is the sloping basal wall of the substructure beneath the north range of columns. The east and west axes of the latter and of the pyramid are not exactly parallel, converging toward the west. Thus the passage is 10 feet [3.1 m] wide at the east and 9 feet [2.7 m] wide at the west. At the western end a poorly built stairway of 12 steps leads up to a platform 28 feet [8.5 m] long and 16 feet [4.9 m] wide, its floor being partly composed of and partly a continuation of the terrace at the top of the first multiple zone on the southern side of the pyramid. That this stairway and platform were built in after the bounding structures were in existence is shown by the fact that the walls of both continue beneath and are hidden by the fill.

The purpose of this stairway and platform is not apparent because there is no doorway giving access to the platform nor any other stairway leading away from it. The western boundary of the platform is a wall composed of two distinct portions. The southern 9 feet [2.7 m] is a right-angled northward extension of the rear wall of the building forming the northern side of the Court of the Columns. The wall then turns at right angles to the west and continues to a junction with the back wall of the Northwest Colonnade. It extends downward past and less than one foot [31 cm] distant from the sculptured band of the first multiple zone of the southern side of the pyramid, and hence is assuredly secondary thereto. If future excavation proves this northern extension of the building is part of the original plan of the North Colonnade, that structure will be shown to have been built later than the pyramid. If it does turn out to have been an addition, other evidence will have to be sought to settle the question of the relative ages of those several units.

The space between the base of the second multiple zone of the pyramid and the aforementioned back wall of the North Colonnade is a blind alley less than 5 feet [1.5 m] in width, bounded at the west by the rear wall of the Northwest Colonnade and at the east by a wall forming the northern portion of the eastern boundary of the platform at the head of the secondary stairway. This alley was never roofed, at least with masonry, and there is nothing to indicate its function.

Considering the unit comprised of the Temple of the Warriors and the Northwest Colonnade as a whole, it is evident that perfection of surface appearance, rather than stability, was the desideratum of the build-

ers. The stones forming the wall faces are very thin, their maximum dimensions being at the margins of the tooled faces where they touch the edges of the blocks above, below, and beside them. The cornice elements are the only blocks with long tenons which firmly tie them into the hearting of the masonry. The effect is much as if one were to remove, with horizontal cuts, the browned top crusts from loaves of bread, and then stand them side by side on end to form a wall face. Such a flimsy shell could have been pried off without difficulty with a sharpened stick.

This lamentable structural weakness is conspicuous in the Ball Court, the Temple of the Jaguars, the different parts of the Group of the Thousand Columns, and to a greater or less degree in all the Toltec-Maya buildings at Chichén Itzá. These stand in marked contrast to such structures as the Monjas and the Akabtzip, which owe much of their preservation to the fact that their massive component blocks reach deep into the hearting.

During the closing period of hybrid brilliance at Chichén Itzá, the Temple of the Warriors must have been one of the most important sacred places in this city of temples. Its position is commanding. Standing beside the Chac Mool midway between the portal and the stair head, one looks past the so-called Temple of the Chac Mool directly into the lower chamber of the Temple of the Jaguars. At the left, the Castillo towers skyward, while nearer by the Group of the Thousand Columns extends far to the south and east. At the immediate right, that is, to the north, lies the Temple of the Tables and not far distant the Sacred Way leading down to the Cenote of Sacrifice. Although built upon a pyramid only half as high, the Temple of the Warriors covers twice the area of the Castillo and in the magnificence and richness of its sculptured ornamentation far excels the higher temple. Indeed in importance it may be reckoned as second only to the Castillo, which was the principal sanctuary of Kukulcan, the patron deity of Chichén Itzá.

38.4.

EARL H. MORRIS

*Report on the Mural Paintings of the
Temple of the Warriors (Station 4)*

YB 24:260–262, 1925

Before the great pyramid at the northeast corner of the Group of the Columns was cleared of undergrowth,

traces of paint were visible upon stones fallen within the last decade from the inner face of the east wall of the Temple of the Warriors upon its summit. Excavation revealed that walls, arch stones, columns, the floor, the altar, and stairway, in short every unit of surface area, had been completely covered with color. Of greatest interest were the frescoes which had decorated the walls and corbelled arches of the temple's interior. In two places it was possible to trace these designs as they appeared *in situ*. The other frescoes recovered were upon fallen wall and arch stones, excavated from the wreckage which filled the temple to a depth of 12 feet [3.7 m]. Nearly a thousand of these latter were recovered, and of these about 850 have been deposited in a storehouse at the hacienda for safe-keeping.

The unfortunate as well as unprecedented hail storm of April 14 destroyed 177 painted stones, but 154 of this number had already been copied in color, thus reducing the total loss to but 23 stones. In all, more than 200 stones were copied by Mrs. Morris during the current field season, and her studies of the decorations of the Temple were of great assistance.

The interior of the temple in ancient times must have presented a sight of barbaric splendor, an almost bewildering array of intricate designs in brilliant colors. The effect of time upon the pigments has softened their sharpness and, while detracting in no way from the brilliance of the original colors, it has enriched and mellowed them.

The surface of the walls was first prepared with lime plaster of a fine, smooth texture, and while this was still wet a general background of solid color was applied. A second, and sometimes even a third, coat was then added. The brush strokes indicate the use of a large, coarse-fibered brush, and in all but one section a thin, very fluid paint. Whether the medium in which the pigments were mixed was water, copal, or some unknown substance, is yet to be determined. In a few instances, the background remained the white-color of the natural plaster, but for most of the frescoes, varying shades of red were used. A few traces of an earlier layer of colored plaster.

The Maya palette presents a wide variation of hues built upon a few fundamental colors. Reds shade from the deepest "Indian red" through the orange reds to a vivid vermillion. Yellows vary from burnt sienna and ochre shades to a pale lemon. Greens and blues are nearly indistinguishable where the color arcs cross, though at extremes of the spectrum nearly a dozen different tones are represented. Black and a light red-dish-tan are invariably employed for outlining. The latter seems to have been first applied to light, plain surfaces with a fine, narrow brush as a complete preliminary outline of the figure to be later filled in with color. The last step was a re-outlining of every detail in

a fairly vivid black. On dark surfaces, the black was utilized for a general preliminary lining only, and after color had been applied without a guide, it had completed the details of the outline.

Owing to the great variation of shades employed, it is probable that most of the tones were acquired by mixing the pigments fresh for each figure or general group. The sources of the colors, with the exception of the red which could have been procured from the bark of at least three different kinds of trees, are at present unknown.

No shading was attempted. The color was laid on flat, and seemingly sufficiently thickly over small areas to obviate the necessity for a second coat. Nor was there need for retouching. The Maya draftsman and colorist wielded a sure brush, sufficiently flexible to limn in a single stroke of the hundreds depicted in the temple, giving to each distinct character and individuality.

The paintings on the walls begin 5 feet 6 inches [1.7 m] from the floor. This basal zone is covered with a dado of broad stripes: 3 feet 6 inches [1.1 m] of black at the bottom, and above this 6 inches [15.2 cm] of blue, 6 inches [15.2 cm] of red outlined in black, 6 inches [15.2 cm] of yellow, and again 6 inches [15.2 cm] of black. An exception to this arrangement is found in the south half of the outer chamber, where the broad bottom band is painted red instead of black. On the surface of the blue, wave-rippled water bordered with white foam, floats a canoe with its prow carved in the likeness of a human head. Nearby, a man is wading and another is swimming. A large fish is also swimming about. Other stones show different species of fish drawn with what seems to be a remarkable fidelity to nature. Sea-weed, jelly-fish, eels, and boatmen, the latter paddling both in standing and sitting positions, are found.

Of equally frequent occurrence are lines of warriors in ceremonial procession, or advancing in double quick time as if to battle. Men in less formal pursuits are also presented, bound as captives, as bearers of the dead, and as carriers transporting burdens by means of the inevitable tumpline.

Genre subjects are found, in a tower-like structure, fenced, henequen plants, houses, a burning roof, and a pot set upon the fire. Tigers, deer, birds, and plants likewise occur, although in more or less fragmentary condition. Of great importance is the omnipresent feathered serpent, which winds throughout the groups more in the spirit of an all-pervading patron deity than as any particular unit of the design, the treatment throughout being free, realistic, and natural.

The two extremes in Maya murals as they are now known are to be found at Tulum and in the Temple of the Jaguars at Chichén Itzá. In the former, the codex-

Figure 38.4.1. Chichén Itzá, Temple of the Warriors, reconstruction drawing.

reminiscent gods strike the last note of ceremonial conventionalization, both in subject-matter and style; in the latter, scenes of ordinary daily life are depicted with a boldness and ease entirely free of conventional crystallization.

The murals in the Temple of the Warriors fall midway between these two. The processional arrangement of elaborately garbed warriors and the invariable speech scroll (both concepts derived from the Toltecs), a uniformity in hair treatment, snakes conventionalized to a state far more decorative than natural, point to an art cast in the mold of custom. On the other hand, everyday scenes, natural posturing, and realistic details occupy at least half of the decorated space.

A diversity of skin pigmentation, within the same groups gives rise to interesting surmises. Men with dark red, tawny, light tan, or blue striped, black, and spotted skins are all to be seen side by side. There seems to be no color differentiation to indicate sex, but beyond this nothing can yet be determined.

Dress and ornament form another interesting study. Fun dress in the formal style includes as a general rule an elaborate plumed headdress, capable of infinite variation, a long feather cape, and a loin cloth. This was varied by the wearing of a single long robe decorated either to resemble the spots of a jaguar skin or a decoration of jade beads, fringed as it reaches the feet. All these garments were flat and stiff, the repre-

sensation of soft drapery falling in folds apparently being beyond the brush of the Maya artist of this period.

A more informal dress consisted of plumed head-dress and loin cloth, or a single white garment of medium length without head covering except, possibly, a close-fitting skull cap.

Lastly, four representations were found of men without any clothing at all, two being stripped from tip to toe. One had his arms bound behind him, the others were obviously ceremonial dancers.

Footgear was invariably the same, except in the case of the stripped captives. The sandal was composed of a sole, a narrow side piece, and some sort of ankle tie. Within these limits, however, infinite variety is achieved.

The figures were usually heavily ornamented. Jade, copper, and gold predominated, with the occasional introduction of some substance colored a vermillion (coral?). The figure wearing the most jewelry had a pair of earplugs, a noseplug, beads in his hair, a necklace and breast plaque, bracelets, anklets, and beads or bells around his knees.

The personal arms borne by the warriors seem to be inadequately represented. Shields and additional long cloth armguards are to be seen, and likewise handfulls of long and short darts, feathered at the shaft and triangularly tipped. In no case is an *atlatl* or spear-thrower clearly discernible, though often gripped in the same hand as the darts one finds an object resembling a throwing stick or boomerang. This may be a conventionalized representation of the *atlatl*, which they undoubtedly possessed.

As the entire temple is studied section by section, the evidence increasingly persuades one that a great number of artists took part in its mural decorations. The individualistic treatment of subjects, coloration, drawing, and general skill add further interest to the interpretation of these paintings.

The decoration of the arched roof was, in general, similar to that of the walls, but on a much lower plane of technical skill. Meticulously treated subjects were avoided and large, simple designs alone appear, and these are marked by distinct crudity. In some cases the paint was applied on the stone itself, hence the preservation of the design has been more complete than on the walls proper.

The base of the exterior wall of the temple sloped at a slight angle to a cornice 4 feet 10 inches [1.5 m] high. This is covered with many coats of plaster. About two-thirds of the way in (that is, from the outside) a design-bearing layer was brought to light. An area 5 feet long of these outer coats was peeled off and copied. These exterior designs were on a large scale and were crude in quality. The section uncovered represented a warrior carrying a large plumed staff (?).

As the rainy season came on, it was observed that the altar in the sanctuary of the temple was being denuded of the plaster coating which carries the painted decoration. Efforts to save this by a generous use of successive coats of ambroid were only partially successful and, in order that nothing might be lost, scale drawings were made of all three elevations and the two interior lines of Atlantean figures, and these were painted in their original colors.

38.5.

EARL H. MORRIS

Report on the Temple on the Northeast Bank of the Xtoloc Cenote (Station 3)

YB 24:263–265, 1925

Mrs. Morris was largely instrumental in carrying on the work which was begun at Station 3 along the cenote's edge on February remains of a stairway were found at this point, and although its dimensions can only be approximated, it was probably about 20 feet [6.1 m] wide and ascended at least 6 feet [1.8 m] by means of eight steps. The top step gave on to a terrace paved with hard, smooth plaster painted red. Later work revealed the presence of an earlier terrace 3 inches [7.6 cm] below the level of the first.

When excavated, the structure facing the cenote was found to have been a temple built in the shape of a "T," the horizontal axis extending from north to south 52 feet 8 inches [16.1 m], the vertical east and west axis being 37 feet 2 inches [11.3 m] long. Owing to the gradual slope of the ground toward the cenote the southern two-thirds of the temple rises from a basal terrace reaching a maximum height of 3 feet [91 cm]. The northern end rests directly upon the ground. Two steps, 29 feet 8 inches [9 m] wide, lead from the terrace to the platform.

Entrance to the temple proper is gained through five doorways in the western façade passing between four round columns with rectangular capitals, and the two adjoining antae. These doorways give into the largest chamber, a colonnaded hall, 48 feet [14.6 m] long and 13 feet [4 m] wide, occupying the entire horizontal axis of the "T," the roof having been supported by six additional columns like those in the doorways,

arranged in a single row down the middle. The free ends of the antae forming the outer door jambs were originally sculptured, but the details have been obliterated by weathering.

In the northeast and southeast corners of the hall, two small benches were found, each 3 feet 6 inches [1.1 m] wide and 1 foot 6 inches [46 cm] high, but of unknown length, since the ends of both had been destroyed in ancient times. It is becoming increasingly evident that such benches were a constant feature of temples of this type, this being the fourth found during the past two years.

Four large flat stones, resembling roof capstones, were found lying side by side, forming a rectangle at the foot of the bench in the southeast corner, though for what purpose it was not possible to ascertain.

Two steps lead up from the eastern side of the colonnaded hall through three doorways into a smaller chamber, measuring 19 feet 5 inches [5.9 m] long by 6 feet [1.8 m] wide. Two square columns carved with figures of warriors and priests, done in a similar though inferior style to those discovered last season at the Northeast Colonnade, form the triple doorway in the west wall noted above.

A finely worked painted capstone was found, in the southeast corner of this middle chamber. Traces of a banding of deep-blue paint still surrounded that part which would have been exposed to view in the finished floor. All further traces of the design had been obliterated.

The only certain example of secondary usage was found in the chamber. Three carved stones, bearing no relation either to the wall or to each other, were found in the eastern wall next to the north jamb of the door leading into the third chamber, or sanctuary.

The sanctuary is the same size as the middle chamber, and was entered through a narrow doorway only 2 feet 6 inches [76 cm] wide, the only entrance to this innermost chamber. These doorjambs were carved in the likeness of men wearing long robes beaded with jade or spotted to represent jaguar skins. The lintel over this doorway was covered with carving of a crude sort, the only discernible parts of the design being portions of a snake's body and, in the lower left-hand corner, two anthropomorphic figures presumably serving a fire burning upon an altar.

Against the middle of the back or east wall of the sanctuary, an altar or raised dais had been built, its front reaching to within 2 feet 10 inches [86 cm] of the doorway. Within this narrow space and directly in front of the middle of the altar, an accidental blow of a pick on the final day of excavation revealed the presence of a small, sealed vault a few inches below the plaster finish of the floor. On excavation this proved to be almost completely filled with earth and stones, but

a few fragments of fragile bones were recovered from the filling. Although final analysis has not yet been made, these bones are believed to be those of a small child.

By far the most notable discovery made in this temple was that the back wall of the arch in the sanctuary immediately above the altar had originally presented a handsomely sculptured panel. Two-thirds of the elements which had composed it were found, fallen within the sanctuary or at a short distance outside, whither they had been carried to build into an old Spanish wall.

The subject matter of this panel has already been described. Of almost equal interest, however, was the highly satisfactory re-assemblage of its scattered and disassociated elements, which it was possible to make, giving its original size and shape, as well as convincing proof of its former position in the now fallen roof of the sanctuary.

As its carved elements began to emerge during the excavation of the sanctuary their similarity of treatment led to the plotting of both their vertical and horizontal positions, each stone being lettered as it came out, and its corresponding position noted. When excavations were completed it was found that 12 sculptured elements had been recovered from the sanctuary, and one from immediately outside.

The close similarity of these carved blocks at first led to the conclusion that they had been removed from a sculptured panel in some other structure, but on account of the unwieldy character of the large, irregular roof blocks, all attempts at fitting them together at first proved unsuccessful. The beautiful character of the relief, however, suggested drawing each element singly to scale, and this procedure was immediately followed by the most surprising and satisfactory results. Reduced to this easily handled form, it became possible to fit most of the fragments together, and this led to the outside of the temple, and to the subsequent recovery of six more, for a total of 19, or about two-thirds of the original panel.

A study of the positions where the 12 blocks inside the sanctuary were found established not only where this panel had fallen from, that is, the back arch above the altar, but also how it had fallen, that is, the topmost elements first and farthest, that is nearest to the doorway. The successive tiers in astonishingly regular order had rested higher and nearer to the arch, until the lowest rows were reached, which, if they had fallen at all, must have remained exposed on the surface of the mound, since these are invariably the elements which were found outside at a distance. Furthermore it is to these lower rows, which were exposed on the surface, that the greater number of the still missing elements are to be assigned.

Elements of the typical three member cornice were observed in the debris outside, but no evidence of further decoration was found.

The work of preservation and repair was confined strictly to saving unstable walls and columns still *in situ*, and to replacing those drums, capitals, and wall stones which had been displaced by the removal of debris in the course of excavation.

38.6.

OLIVER G. RICKETSON

Report on the Repair of the Caracol

YB 24:265–267, 1925

The condition of the building called the Caracol was noted as in “urgent need of immediate repair” in 1924. As a result of this examination and further study early in the season of 1925, a statement of the specific repairs contemplated, accompanied by diagrams, was sent to the Department of Anthropology in Mexico with a request for permission to do this work at once, in order to prevent the collapse of the structure. Permission having been granted, the work was carried out with three objectives in view: 1. To prevent the collapse of Window no. 1; 2. To support the outer wall on the west, and 3. To support the outer wall on the southeast. The complete erosion of the original mortar in these last two areas necessitated the removal of dirt and fallen stones, and the replacement of stones *in situ*, laid in cement.

It was felt that the preservation of Window no. 1, long suspected of having been used as an observatory, was the most important operation. This aperture is a rectangular passageway, 8 feet 3 inches [2.5 m] long, 2 feet 10 inches [86 cm] high, and 2 feet 3 inches [69 cm] wide, facing W 8 degrees 30' N (magnetic). The western jamb was found to be leaning toward the west so that it was 6 inches [15.2 cm] out of plumb, and the northern jamb of the eastern end rested precariously on a single rock, itself without any solid foundation. To build a buttress in order to support this latter, it was first necessary to develop a base sufficiently solid by repairing the west wall.

Work was consequently begun at this point, directly over the West Doorway. Two conditions hitherto un-noted were revealed: 1. The necessity of obtaining faced wall-stones by searching and digging in the fallen

debris to west of the building, and 2. The extraordinarily precarious condition of the inner wall of the outer circular vault.

These conditions were overcome by building up the outer wall three courses above the 5-member cornice. Wall stones from the debris below were used, and need not be replaced when final repairs are undertaken. The second condition was the more difficult of solution, as the removal of a single vault stone would have brought down the whole top. Nor could the debris above be removed, as it was the weight of this pressing down on the tenons of the wall-stones that prevented the vault itself from collapsing. Cement was forced into the spaces between the stones; after this hardened, all above was removed as far as possible, and more cement poured tenons of the vault-stones.

The cap-stones above the vault of the inner circular corridor in the northern quadrant having fallen, these were replaced laid in cement, and from these two solid foundations a “skin” of cement was built up around rocks in position until a firm support could be placed under the eastern jamb of Window no. 1. The whole top of the structure was then cemented to prevent erosion by the heavy rains, the cement being worked in between the stones after the original crumbling mortar had been removed. In this work only loose, superficial stones were removed, and no effort was spared to maintain original stones in their original positions.

The third and last area of repair mentioned above was the outer wall on the southeast. Inasmuch as the tenons of the vault-stones were exposed here the work consisted entirely in the filling-in of intervening spaces with cement and small wedges.

During the excavations for wall stones a small vase was found intact. It was of a burnished ware with a metallic luster.

The removal of the loose, superficial dirt and stones revealed three new constructions of interest, whose functions, it would seem, could only have been for making astronomical observations.

The first of these is Window no. 2 (Maudslay 1889–1902:3: Plate 21) has a photograph which shows Window no. 2; Stephens (1841:2:298) also figures a drawing clearly showing Windows nos. 1 and 2. It is a small, rectangular passageway, 9.5 inches [24 cm] wide, 1 foot 2 inches [36 cm] high, and 5 feet 2 inches [1.6 m] long in the mid-line, bearing S 42 degrees W (magnetic). As it is level, a view through it intersects the horizon, giving a maximum angle of vision, that is, by moving the eye from one diagonal to the other, of 20 degrees 45'. The maximum angle of vision vertically is 15'.

The second construction was a third line-of-sight, called Window no. 3. It too is a small, rectangular pas-

sageway, 6 inches [15.2 cm] wide, 1 foot 1 inch [33 cm] high and 6 feet 4 inches [1.9 m] long. Through this aperture the maximum horizontal angle of vision is 10 degrees 45', and the vertical angle 23 degrees.

Both of these constructions emerge through an interior wall to the east and south of Window no. 1, which, with what is left of the interior wall on its north, presumably indicates the former presence of an observation chamber at this point, now, however, entirely destroyed except for this southwest corner; and further that the probable entrance to such a chamber was by way of the spiral staircase in the core of the building.

The third construction uncovered was a circular vertical shaft, roughly a foot [31 cm] in diameter, extending down through the core. No estimate of its depth could be made, as a plumb-line was stopped at about 6 feet by washed-in earth; water, however, poured down the shaft came out the core into the inner circular corridor at the spring of the arch. Complete excavation will be necessary to determine whether or not this shaft leads into a central room located in the masonry of the core, and if so, whether or not it could possibly have been used for the meridian sight of any celestial body.

Observations were made through Window no. 1 at frequent intervals. The maximum angle of vision on the horizon is 30 degrees. It was noted that the sun set on the diagonal drawn from the northeast corner to the southwest corner on March 21, 1925, that it passed northward 15 degrees and set along the midline on April 28, 1925, and that it then continued northward going 5 degrees south of the diagonal drawn from the southeast corner, and the southwest corner on June 22, 1925. The function of this window as a solar observatory for determining the summer solstice and the equinoxes would seem, therefore, to be established.

The results of these field observations at the Caracol were sent to the Department of Terrestrial Magnetism for analysis and the Director, Dr. Bauer, under date of June 24 has written Mr. Ricketson concerning them as follows:

The description of the windows of the Caracol as given in your letter of May 30 is interesting evidence of a knowledge of practical astronomy among the early inhabitants of Yucatán. In the following notes the jambs are designated right and left as when looking out, and azimuths or directions are astronomical: a. Window 1. The direction, right inner jamb to left outer jamb is due west; b. Window 3. The direction, right inner jamb to left outer jamb is due south; c. Window 2. The direction, left inner jamb to right outer jamb is in azimuth 59 degrees reckoned westward from south or in amplitude 31

degrees; and d. Window 1. The direction, left inner jamb to right outer jamb has the same amplitude north of west (31 degrees) as c is south of west. The amplitude of the Sun at setting on March 21, was 0 degrees or due west which accords with the direction under a. On April 28 its amplitude was 15 degrees north of west, hence it appeared exactly down the midline of Window 1 as you observed. The Sun's amplitude on June 21 at Chichén Itzá is 25 degrees, consequently it will not be seen setting in the direction given under d as you anticipated, but about 5 degrees further to the left or westward. The directions c and d are the directions of the Moon at setting when its ascending node is in the vernal equinox; that is when its declination is a maximum, about 28 degrees 36'. Nothing apparently marks the direction of its setting 9.5 years later when its maximum declination for the year is reduced to about 18 degrees 25' and its amplitudes became 20 degrees north or south. Window 3 is not high enough for direct observations of the Sun at noon or the Moon at meridian passages; hence, if it was constructed for such observations, it must have been the shadows of the jambs cast by the Sun or, Moon that were noted. Directions a, b, c, and d mark astronomical directions of local importance whether intentionally or unwittingly, but two directions remain for which I can assign no reason at the present time. The above directions have been computed with the assumption that the Sun and Moon set over a practically level stretch of country. It is possible that nearby mountains, deep valleys, or other landscape features, of which we have no information, might alter the computed directions several degrees.

It should be noted that inasmuch as the country surrounding Chichén Itzá is literally as flat as a tabletop, no correction for neighboring topographic features, as suggested in the last paragraph above, has to be applied to the figures given.

In conclusion attention should be called to the fact that the stones framing the eastern or "observation" end of Window no. 1 were cemented as they stood, no attempt being made to correct their positions even though the correction was obvious, so that all future observations may be made without fear that the corrections in the positions of the stones has in any way been conducive to or suggestive of spectacular or desired conditions.

38.7.

OLIVER G. RICKETSON

*Report on the Temple of the Four Lintels
(Station 7)*

YB 24:267–269, 1925

This small temple in Old Chichén Itzá is a rectangular structure 41 feet 9 inches [12.8 m] long, from east to west, and 16 feet 10 inches [5.1 m] wide. It stands on a low platform roughly 20 inches [51 cm] high, 81 feet [24.7 m] long east and west, and 66 feet [20.1 m] wide. The temple faces north, the principal entrance being opposite two steps in the center of the north side of the platform. Directly in front of the entrance, 3 feet 6 inches [1.1 m], is another step, 10 inches [25.4 cm] high, and at the very threshold another step of the same height. The doorway is double, having a massive central column of three square blocks, each 33 inches [93.8 cm] square by 21 inches [53.3 cm] high. Above these there is a rectangular capital 39 inches [99.1 cm] square and 8 inches [20.3 cm] high, and below is a corresponding pedestal. This square column is flanked on either side by a doorway, 6 feet [1.8 m] high and 3 feet 6 inches [1.1 m] wide. The outer jambs of both of these doorways consist of two hewn monoliths, one for each opening, 6 feet [1.8 m] high, 1 foot 6 inches [46 cm] wide, and 2 feet 9 inches [84 cm] deep. The lintels above these two doorways are each of a single piece of stone bearing hieroglyphs in panels on their soffits and external (northern) faces. The lintel (no. 2) over the east doorway is 4 feet 3 inches [1.3 m] long, 10 inches [25.4 cm] high, and 2 feet 7 inches [79 cm] deep, and the lintel (no. 3) over the west doorway varies from its mate only by fractions of an inch.

In the excavation necessary to free the fallen western monolithic jamb and to clean the area directly in front of the temple, a total of 11 carved stone heads with depressions in the top were found. All of these were found right-side up, so that it might be inferred that they occupied their original positions, being covered with fallen debris, and that they did not themselves fall from above. By far the greater proportion of them had the “twisted doughnut” ornament, usually associated with Tlaloc, the Rain God.

Inside, the temple is divided into at least two rooms,¹ the smaller of which lies at the east end. It is 12 feet [3.7 m] long, and 8 feet 9 inches [2.7 m] wide, the entrance to it being through a doorway opening from the larger western chamber of the temple. This doorway is 3 feet [91 cm] wide, and the lintel above it is carved with hieroglyphs on the soffit and on the side facing the interior of the temple, that is, west. The wall

pierced by this doorway bears a three member medial cornice, a type of decoration found on the outside of buildings. Its presence here, on an inner wall, is not explicable, especially as it could not be determined by the jointure of the stones in the corners that this small chamber represents an older temple to which had been subsequently added a newer construction to the west. Also, the dates of all lintels in this temple are the same: 11.9.13.0.0. In this doorway was found a coarse red bowl.

The fourth and last lintel spans a doorway 2 feet 6 inches [76 cm] wide, which pierces the western wall. It, like the others, bears glyph-panels on its soffit and on its external (western) face.

In concluding, it might be added that the massiveness of the rectangular column in the main entrance, the unusually large size of the wall-stones, and the great length of their tenons, all argue that this structure (or at least the materials of which it was made) is of an earlier epoch than the Toltec period at Chichén Itzá, when smaller building blocks were used.

Less than 200 yards [183 m] to the south, another small rectangular temple with three rooms was noted. It also faces north, and is 57 feet [17.3 m] long, east and west. The entire front of this building having collapsed, it was inferred by the intact back and partition walls of its three rooms that access to them must have been through the three main doorways in the front, the plain lintels of which were all found. The south or back wall still standing, however, gave evidence of elaborate decoration; this consists of a band of column-like carvings in low relief and great areas of wall-stones carved in a denticulate design, resembling a similar decoration in the Monjas.

Both of these structures from the style of their architecture as well as from the dates on the hieroglyphic lintels would appear to date from the Middle Period of the city's history, from 965 to 1191 AD, that is, during the second occupation but before the advent of the Toltec conquerors.

NOTES

1. The complete excavation of the temple was not attempted, work being confined to that necessary for replacing the hieroglyphic lintels in their original positions on the door jambs.

38.8.

KARL RUPPERT

Report on the Secondary Constructions in the Court of the Columns

YB 24: 269–270, 1925

On April 14, there occurred at Chichén Itzá the heaviest hail-storm within the memory of anyone living in the region. The individual, hail-stones, were in many cases 1.25 inches [3.2 cm] in diameter, and such was their size and number that they had not entirely melted 24 hours later.

The most striking effect of this fall of ice was that it literally beat the forest bare. Scarcely a leaf remained on a tree; the bush in every direction looked like a December landscape in the United States, the trees gaunt and naked, stripped completely of their foliage. Even the undergrowth, bushes, vines, grasses, etc., were beaten to the ground until the city was exposed to view, as doubtless it had not been since the days of its final abandonment in the middle of the fifteenth century.

This general denudation and clearing of the ruins brought to light many hitherto unsuspected archaeological features, among others a number of low secondary constructions in the Court of the Columns and advantage was taken of the unique opportunity to make a preliminary survey of them before they should have disappeared again beneath the swiftly growing bush.

The survey revealed about 58 structures and mounds which may be classified according to shape as: 1. Rectangular, 2. Round or oval, 3. Irregular, 4. L-shaped, and 5. Square. The structures are somewhat unevenly arranged in the court in four great rows, extending from north to south.

There are 25 rectangular structures which vary in size from no. 1, the smallest, which is 3 by 8 feet [91 cm by 2.5 m], to no. 4, the largest, which is 34 feet 8 inches [10.6 m] by 13 feet 9 inches [4.2 m], the long axis of 19 of them being east and west. In some cases, they are composed only of an outline of unworked, worked, and even discarded sculptured stones set in the ground, level with the Court floor. In others the outlining stones may be one, two, or even three tiers high, in which latter case the enclosed area has been filled. When the enclosed area is level, or not more than 6 inches [15.2 cm] above the court floor, in many cases it is paved with discarded wall stones. Two structures in diagonal corners of the court bear striking similarities. In the northwest corner, no. 3 is composed of rectangular column blocks, and no. 4, in the southeast corner is made of seven rectangular column blocks.

Both are arranged in the form of a rectangle with an average length of 5 feet [1.5 m] and a width of 4 feet 5 inches [1.3 m], their long axes being east and west. The enclosed area in each is raised a foot [31 cm] above the level of the court floor; and each has a cylindrical column drum in its center.

Structures 11, 20, 21, 31, 52, and 23 are L-shaped. The last two may prove on excavation to belong to another group. In each case the base of the "L" is toward the east, with the long arm along the south. No. 11 is the largest of these L-shaped structures. It is raised a foot [31 cm] above the court floor level, and is paved with wall stones except in the southeast corner, where column drums have been set in the floor for that purpose. The long arm of the "L" toward the west is not paved, being merely outlined by a row of cornice and wall stones. This structure measures 55 feet [16.8 m] on the south, 21 feet 8 inches [6.6 m] on the east, 13 feet 9 inches [4.2 m] at the north end of the short arm, and 11 feet 6 inches [3.5 m] at the west end of the long arm.

Five of the structures at present fall into the square group. The best preserved of these is no. 22, in the southwest corner between what may be a small ballcourt and the south end of the West Colonnade. It is formed by a low terrace, 45 feet [13.7 m] on the east, 44 feet [13.4 m] on the south, 46 feet [14 m] on the west, and 43 feet [13.1 m] on the north. A small temple had been built on this terrace, of which the talud and cornice still remain. The entrance is from the east.

Structure no. 45, along the south edge of the court, consists of five circular stones that have been set in the floor of the plaza in two rows extending north and south. The stones average one foot [31 cm] in diameter and each has an aperture in the center, 6 inches [15.2 cm] in diameter. These stones may well have been supports for awnings or flag-staffs. Another group of similar perforated circular stones is known to have existed formerly in the central part of the court, but only one of these now remains *in situ* (no. 14).

The round or oval-shaped structures are mostly mounds in which the outlining walls are not easily discernible. Of this class, four out of seven have their long axes east and west. The largest, no. 34, is located in the southeast quarter of the court. It is oval in shape, rising 2.5 feet [76 cm] above the plaza level, and measures 17.5 feet [5.3 m] north and south by 15 feet 5 inches [4.7 m] east and west. This mound is formed both of large dressed blocks and crude unworked stones.

There are 15 structures belonging to the irregular group. These are mostly mounds which on excavation will fall into one of the other classes. The shape of no. 32 is not well indicated. The east, north, and west sides are straight, with the south side rounded. The mound measures 24 feet [7.3 m] north and south, and 18 feet

[5.5 m] east and west and is raised 3 feet [91 cm] above the plaza floor level. On the west side, just north of the curved outlining wall, is what appears to be a series of three steps. Mr. Morris made a test pit in the northeast corner of this mound in 1924, exposing a group of column drums. One other structure, no. 8, was partially excavated by Mr. E. H. Thompson some years ago. This area measures 13 feet [4 m] by 12 feet [3.7 m] and is now marked by an oval depression in which a cache of column drums was found. With the exception of these two mounds, no excavation has been done in the court.

Perhaps the most salient feature of most of these low constructions is the very general presence in them of re-used material from other buildings, such as sculptured blocks, column drums, wall, and cornice members. This secondary usage of earlier building elements argues for a comparatively late origin, which is in keeping with the crude masonry characterizing them. Indeed, it seems fairly safe to conclude that they date from a period when the city, having already passed its zenith, was on the decline, and in some cases they may even date from post-Conquest times.

It has been suggested that they were house foundation-platforms, dating possibly from as late as the Spanish Period, or that they were market-stalls, the surrounding court being the great market-place of the city in ancient times, or again that they were dance platforms such as Bishop Landa describes, or even places where sacrifices might have been made in public. But the correct explanation of their former use must await further excavation and study. Such is their number and location, in the very center of the Group of the Thousand Columns, that it would seem advisable to continue, the investigation of these structures so happily exposed by the great hail-storm of April 14.

38.9.

SYLVANUS G. MORLEY

Archaeology

YB 25:259–273, 1926

With the current field season (ending June 15) the Chichén Itzá Project has completed its third year and is now fully organized. The staff for 1926 was as follows: Sylvanus G. Morley, in charge; E. H. Morris, archaeologist in charge of excavations; Karl Ruppert,

assistant archaeologist; G. C. Vaillant, assistant archaeologist; J.E.S. Thompson, assistant archaeologist; Jean Charlot, artist; Mrs. E. H. Morris, artist; E. L. Crandall (U. S. Department of Agriculture), photographer; Juan Sopena, assistant photographer; and Miss Katarina Jameson, secretary and bookkeeper. Miss Jameson was obliged to return to the United States in March owing to illness, and her duties for the last half of the season were discharged by Mr. Ruppert and R. A. Franks, Jr.

Dr. Morley left Washington on December 15 for Mexico City, to confer with Mr. José Reygadas Vertiz, the Director of Archaeology, as to the plans for the current season. While there he delivered two illustrated lectures in Spanish under the auspices of Dr. J. M. Puig y Casauranc, Minister of Public Education; one on the work of the Institution at Chichén Itzá during 1925, and the other upon the Maya and Aztec hieroglyphic writing. These lectures were broadcast from the sending station at the Ministry of Public Education, and were heard in Yucatán.

In addition to the regular members of the staff, the Chichén Itzá Project has received valuable field assistance during the year from outside sources. In January, Mr. Clarence Hay, Research Associate in Mexican and Central American Archaeology of the American Museum of Natural History, New York, visited Chichén Itzá, for the purpose of studying the façade of the Temple of the Warriors, to ascertain whether or not it would be feasible for reproduction in facsimile in the projected Mexican Hall at the American Museum. He found that the dimensions of its façade are such that it may be reproduced in full size in the space available for this purpose.

Mr. Hay was accompanied by Arthur Austen of the Fogg Museum of Harvard University, an expert in removing frescoes. Through the courtesy of Mr. Edward A. Forbes, Director of the Fogg Museum, Mr. Austen spent 10 days at Chichén Itzá and tried out several different processes for removing the paintings on the fallen wall stones from the Temple of the Warriors. These experiments were only partially successful, owing to the extremely enamel-like quality of the Chichén Itzá plaster, which last year proved impervious even to ether, the solvent of ambroid, and this year, to glue and, water. Mr. Austen is of the opinion, however, that further laboratory work may improve the technique sufficiently to permit its successful application to the Chichén Itzá mural paintings.

Dr. F. I. Proctor visited the ruins in January, making extensive experiments in the use of stereoscopic photography. Highly satisfactory results were obtained, particularly in the copying of hieroglyphic texts, the full value of the relief being rendered with life-like accuracy; and it would appear advisable to continue this work in the future.

Dr. Thomas Gann of British Honduras arrived at Chichén Itzá early in February, and accompanied Mr. Crandall on the Institution's First Expedition to the ruins of Cobá. Dr. Gann reports the discovery by him of a new hieroglyphic stela at a site on Chetumal Bay in southeastern Yucatán presenting the fifth Initial Series yet to be found in the entire peninsula. This records the early date 9.8.0.0.0 (approximately 334 AD)[Chapter 1.12].

In February, Joseph Linden Smith, the well-known artist and delineator of archaeological subjects, was the guest of the Institution at Chichén Itzá, for two months. During his visit he painted 11 pictures, showing details of the sculptural decoration, bas-reliefs, etc., from the Temples of the Warriors, Jaguars and Initial Series. He also accompanied Dr. Morley on his trip to Copán in April and painted two full-size pictures of Stelae H and N there. The first public showing of these canvases was at the Annual Reception and Exhibition, held at the Administration Building on the evening of December 10.

In March Mr. Ignacio Marquina, architect of the Department of Archaeology, came from Mexico City to inspect the excavations and repair work, and also to consult with Dr. Morley as to where and how the Department might most advantageously use the \$8,000 it is to expend at Chichén Itzá annually, as provided for under Article 27 of the Institution's contract with the Mexican Government.

Dr. Walter Lehmann, of Berlin, and Dr. H. J. Spinden, of the Peabody Museum of Archaeology and Ethnology at Harvard University, also visited Chichén Itzá, in March. The former made copies of the mural paintings and bas-reliefs in the Temple of the Jaguars, and the latter a special study of the hieroglyphic lintels.

Under an arrangement with Dean Edgely of the Harvard School of Architecture, Dr. Kenneth J. Conant of the University faculty visited Chichén Itzá at the end of May and early in June and made four architectural drawings of restorations of the Temple of the Warriors, the Caracol, and the Northeast Colonnade. Perhaps better than any other form of presentation, short of an actual model, an architectural drawing shows the original appearance of a building; and Dr. Conant's restorations of the Temple of the Warriors and the Caracol convey a vivid impression of the former magnificence and dignity of these structures.

Excavations at Chichén Itzá, during the year, were carried on at four different stations: The Temple of the Warriors (Station 4); The Northwest Colonnade (Station 10); The Caracol (Station 5); and, The Group of the Initial Series at Old Chichén Itzá, (Station 13).

A special report covering excavation activities at the Temple of the Warriors and the Northwest Colon-

nade [has been prepared] by E. H. Morris, archaeologist in charge of excavations.

THE TEMPLE OF THE WARRIORS

The most notable find of the year at Chichén Itzá was the discovery of the serpent columns and sculptured door jambs of an earlier temple had been partially destroyed and partially incorporated in the northwestern corner of the pyramid supporting the Temple of the Warriors, Station 4.

A single column of this temple had been exposed last year [Chapter 38.3], but it was not until the excavation of the northwestern corner of the pyramid was commenced at the close of the present season, that these additional façade elements were found.

The two heads and two tails of the pair of feathered-serpent columns, which had stood in the entrance of this earlier temple, all 4, slightly broken, were recovered, just where they had been built into the hearting of the later pyramid; and in this same rubble fill, arranged in the form of a low bin or rectangular enclosure, were found the sculptured blocks which had formed two jambs of the same doorway.

Three painted and sculptured columns belonging to the row behind the serpent columns and a section of the southern wall, 8 feet high, were found *in situ*, all brilliantly painted.

Never before has such vivid coloring been exposed at Chichén Itzá. This early temple must have had a fresh coat of paint shortly before it was destroyed in ancient times, and the rubble hearting of which these blocks formed a part has kept them from sunlight and weathering so that their colors, red, green, black, yellow, and blue, seem to be preserved almost at their original values.

One interesting feature noted was that the eyes of the human figures had been deliberately gouged out as though they had been made of some more precious material, which it was desired to save for use elsewhere. This is partially confirmed by the fact that one of the 92 human figures on the columns of the Temple of the Warriors still retains its eye made of an incrustation of mother-of-pearl with the pupil of obsidian or hematite, whereas all the other human figures in this temple had had their eyes gouged out. These blocks were removed to the church at the hacienda for safe-keeping and placed in a darkened room.

Scarcely less remarkable was the discovery of a magnificently sculptured and painted dais, 16 feet 6 inches [5 m] long, 13 feet 2 inches [4 m] deep, and 2 feet 10 inches [86 cm] high, built against the back wall of the Northwest Colonnade (Station 10) just south of the stairway leading to the Temple of the Warriors.

This dais is almost identical with the one found in

1924 against the back wall of the Northeast Colonnade [Chapter 38.1], except that the one found this year is in a perfect state of preservation, not a single sculptured element being missing. Without doubt it is one of the most remarkable productions of Maya art yet brought to light at Chichén Itzá.

The cornice or molding shows the same treatment as the corresponding element in the dais in the Northeast Colonnade: pairs of plumed rattlesnakes facing each other, from whose mouths issue human figures visible to the waistline, which in turn face tripod bowls filled with small round cakes of copal incense.

Jean Charlot, one of the staff artists, made a color copy of the figures in oil, original size, shortly after the dais was first uncovered and while the pigments still retained much of their original brilliancy. In describing the paintings, he says:

The most striking feature of this platform is the excellent state of preservation of its paintings. The floor of the altar is painted red like the floor of the temple.

The cornice presents a group of gods in human shape, holding arrows and atlats (throwing sticks). They are seen only to the waistline as they emerge from the open jaws of feathered serpents. They seem to receive the smoke of copal incense offered in painted ceremonial bowls. The snakes are alternately green, black and white with yellow bellies. The background is red and the border blue. The sloping sides of the platform are carved with processions of men, probably warriors and priests, marching from the back wall toward the front and from the sides to the center. These figures vary greatly in costume and attributes. Behind some of them stand rattle-snakes curved in an S shape, while others have headdresses made of blue feathered masks of the Long-nosed God, and carry long ceremonial sticks tipped with flowers.

The figures also have flowers on their heads, and their short dancing skirts, curved like petals, probably suggest the same motif. The background is filled with ornamental devices. The dominant colors are blue, red, yellow, green, black and white. This platform is one of the best-preserved examples of painting combined with sculpture yet found at Chichén Itzá.

In reporting the results of his study of the sculptured columns in the Temple of the Warriors, Mr. Charlot makes some interesting observations on the technique of Mayan artists:

The columns are made of a relatively soft white limestone, each column being composed of an arbitrary number of square drums, whose height varies from 20 cm to one meter. These

drums are joined by lime mortar, and the space between is filled with stucco, modeled to connect the sculptured designs on contiguous stones, some of it still being in place. The carving was done with a tool little harder than the stone itself, if one may judge by the irregularity of the curved lines and an evident concern to avoid deep carving and spheric modeling. The drums were put in place before carving, and the design was then sketched upon the flat surface of the stone and the silhouette of the figure was brought out by cutting in the background a centimeter or two. Inside lines were cut by diagonal incisions, and the lightest lines were made by scratching only. The apparent primitiveness of this technique, however, must not be charged to any incapacity on the part of the ancient craftsman, who had skill enough, when he chose to exercise it, to carve in full round the Atlantean figures of the altar and the beautiful seated figures of the façade.

This primitive character of the relief would seem to be due to the fact that the carving on the columns was considered only as a sort of skeleton to be entirely covered with painting. The suggestion of depth, correct drawing and the details were to be worked out with paint, so much so that, in the darker parts of the temple, the sculpture was limited to a few rough lines scratched on a surface covered with stucco.

The painter, who followed after the sculptor, worked with two kinds of colors; one opaque and sufficiently solid to be applied directly to the surface of the stone and sometimes used only as a background for finer colors; the other, applied *alfresco* on a preparation of white which showed through the transparent color, the same effect being obtained by this treatment columns, as in the case of the wall paintings. The line is elegant, tapering from broad to narrow by imperceptible nuances. This and the boldness of the curves shows that the brushes must have been of carefully chosen long hairs pointed when wet, as a Japanese water-color brush.

The colors used are the following: an opaque, dull red, near the Indian red, made from an indigenous wood, which is still used in wall-painting. This red forms all of the backgrounds, and, since it is one of the most permanent colors, still retains in practically all places its original brilliancy. There is a blue, which when opaque is like a kind of dark Prussian blue, and when transparent more nearly a cerulean blue. This color was used for all the borders around the pictures; it is the dominant note in the ensemble and is especially associated with sacrificial ceremonies. A green, a yellow and a black complete the palette. These colors were so much varied by mixing, how-

ever, that in practice the number of colors is unlimited.

The colors were not applied in flat tones, but were irregularly distributed, the brush strokes suggesting movement and depth. Black or red lines, drawn freely on colored background, indicate such minute details as the individual feathers or stones in a mosaic, the thongs and polychrome designs of sandals, finger-nails, hair and eyebrows. Different layers of color can be distinguished one from another; the latest layer being especially characterized by a preponderance of black and white.

The sculpture, in addition to painting, was enriched by incrustations of mother of pearl, obsidian, and very probably of colored beads, the places of which are now shown only by empty holes in the surface of the stones. In addition to diversity of interest, polychromy also added clarity, for each object was traditionally of a certain color, and this together with the outlining gave definition to and emphasized each object. Feathers were green or blue; jewels, when turquoise, are blue, but green, when malachite or jade. Yellow was used to indicate gold or copper. The greatest variety is to be noted in the colors of the skin, which run from a sort of grayish yellow to black, through all shades of red. Even bodies of pure blue or striped red and white can be found. Such differences would be hard to explain ethnologically and to understand them one must remember the war-paints and tattoos of which the early Spanish writers give full descriptions.

Continuing the policy established during the 1924 field season of reconstruction only within the bounds of virtual certainty, the work of reassembling the sculptured elements of the Temple of the Warriors was continued during the 1926 season.

In excavation the greatest care was taken to keep the individual sculptured stones as near as possible in the relative positions in which they were found, and this proved of invaluable assistance in placing the stones in their original places in the friezes, masks and panels.

The enormous task of fitting together and assembling the sculptured elements of these different bands, masks and panels was performed by several members of the staff during the last two seasons.

In 1925, Messrs. Morris, Ricketson and Ruppert devoted time to this difficult work, and this year Messrs. Ruppert and Thompson were thus very largely engaged. Mr. Ruppert spent practically all his time during the last half of the season fitting together the masks and serpent-bird panels in the Temple of the Warriors, and supervising their replacement in the walls, and Mr.

Thompson devoted fully half of his time to the bands on the northern and southern sides of the pyramid.

Karl Ruppert, assistant archaeologist, in discussing the details of this work reports in part as follows:

The sculptured elements at the Temple of the Warriors which it has been possible to replace may be divided into two groups: those coming from the pyramid and those from the temple proper which surmounts the pyramidal base.

Excavations during the 1925 season had revealed the pyramid as composed of four terraces made up of the following elements: 1. a battered wall 5 feet 6 inches [1.7 m] high, which rises with a gradient of from 65 degrees to 75 degrees from the horizontal, varying according to the side of the pyramid and the particular terrace; 2. above this a vertical cornice 6 inches [15.2 cm] in height and projecting from 6 to 7 inches [15.2–17.8 cm]; 3. 2 inches [8.1 cm] back from the upper margin of this cornice is set an elaborately sculptured band formed of two courses of stone, 2 feet 3 inches [69 cm] to 2 feet 6 inches [76 cm] in height, which in turn is surmounted by 4. a second vertical cornice also 6 inches [15.2 cm] length, the upper margin of which forms the level of the terrace top.

In the case of the three lower vertical bands (no. 2 above), portions of the sculptured elements were found *in situ*, which gave the clue for the reassemblage and replacement of the design. No portion of the fourth vertical band, however, was found *in situ*, but such is the scarcity of sculptured stones remaining after the three lower bands had been returned to their original positions, it hardly seems possible that it could have been sculptured like the corresponding element in the three lower terraces.

During the 1925 season the third band, with the exception of two stones which were not found, was replaced on the west side south of the stairway. As the Northwest Colonnade abuts the pyramid supporting the Temple of the Warriors on this side, the first and second vertical bands do not appear. After the replacement of the third band only three sculptured stones remained which could possibly have belonged to a fourth vertical band. This practically eliminates the possibility that the fourth vertical band, which was nowhere found *in situ*, could have been sculptured.

The lowest sculptured band on the south side of the pyramid measures 125 feet 4 inches [38.2 m] long and 2 feet 6 inches [76 cm] high. Its western end abuts against the east side of the north and south wall which forms the back of the Northwest Colonnade. The western 75 feet [22.9 m] of this band was found *in situ*, having

been covered by a colonnade south of it, which had been built against it. The remaining 50 feet 4 inches [15.3 m] to the east was fitted together and put back into place, and is composed of 91 stones.

The second band on the south side is 117 feet 3 inches [35.7 m] long and 2 feet 6 inches [76 cm] high. It is composed of 250 stones, 116 of which were *in situ*. Of the remaining 134 fallen stones, it was possible to recover and replace 132.

The third band is also 117 feet 3 inches [35.7 m] long and 2 feet 6 inches [76 cm] wide and was composed of 254 stones, of which but five are still lacking.

The same relative lengths hold for the bands on the north side of the pyramid. Here, however, only in the case of the lowest band at the west end were stones found *in situ*, from which point the band could be extended.

In the case of the first and second bands on the north side it was necessary to leave a break of 3 feet 10 inches [1.2 m] and 39 feet 8 inches [12.1 m], respectively, in order to show the remains of the east wall of an earlier pyramid which had been covered by the later pyramid.

The design of the sculptured elements is a repetition of alternating pairs of semi-reclining warriors and pairs of animals, or bird and animal figures. The figures of the warriors are placed feet to feet, their faces looking away from each other. In every case they carry long plumed spears, or staffs, which in the various bands show considerable stylistic differences. The relief is low, but very distinct. The warriors wear elaborate costumes which still show traces of blue, red and green paint. The warriors in the lowest band are more recumbent than those in the other two bands, and also the staffs are held at a greater angle. The distal end rises to the height of the warrior's head, while the other end is quite low. The feather ornaments on the staff swing low and away from the body. The *maxtli*, or Mayan breech clout, also curves sharply away from the body to accommodate itself to the reclining position of the figure.

In the first and second bands the plumes on the end of the staff divide, a single plume curving up and back toward the rear of the warrior's head, the other three turning downward. The ornaments, or scrolls, at the opposite end of the staff are long and slender and generally swing away from the figure. The *maxtli* is long and swings away from the warrior's body.

In the third band the warriors are more upright and the staff is held almost horizontal. The plumes at the end of the staff turn up in a single group of 3, 4 or 5, and curve toward the back of the warrior's head. A pendant grouping of plumes on the staff, which in the case of the

lower bands swings away from the warrior's body, here always hangs perpendicular.

The bird figure is that of an eagle. The animal figures are those of the jaguar, and a still unidentified short-tailed, thick-haired quadruped, called by the native laborers a bear, which it in no small degree resembles. The figures are squatting on their haunches and hold in their forepaws an object which they appear to be offering to the warriors, whom they face. In general, the animal and bird figures are found in pairs with their backs to each other. In no case has a pair of like animals or birds been found together. On the western side of the pyramid in the third and only sculptured band found there, one instance was noted where a jaguar and eagle face each other. Another variant was noted in the arrangement in the first band on the southern side, where two pairs of animal figures appear next each other. There seems to be no stylistic difference in the animal or bird figures of the different bands. Speech scrolls, circles and ornaments fill the background.

The bands have been carefully painted and replastered several times. The background is red; the warriors have head-dresses of green, red and blue; and dresses of green, yellow, red and blue. The eagles are red; and the tigers, yellow, brown and black.

On the western side of the pyramid, where the southern portion of the band that extends under the stairway is still *in situ*, one of the stones was actually found upside down. This clearly indicates that the stones were sculptured before being placed in the bands.

Lying spread out on the ground in the bush a short distance northwest of the pyramid is an elaborate sculptured band partially fitted together, as if this may have been the workshop for building operations going on at some other temple. Here the sculptured stones are laid out in order, seemingly as if the workmen were fitting them together at this point, preliminary to their being placed in the walls of some building under construction in the immediate vicinity.

The only examples of re-used stones found in the vertical bands were in the lowest bands on the northern and southern sides, where large roof cornice stones had been re-used.

The sculptured elements in the Temple of the Warriors proper, which were replaced this season, were all elements of the lower vertical zone of the façade and are located as described by Mr. Morris in [Chapter 38.4]. They may be divided into two groups: masks and serpent-bird panels.

The masks are grotesque faces, front view, built up of separately carved blocks, and they fill rectangular spaces. They average 6 feet 2 inches [1.9 m] wide by 3 feet 2 inches [96 cm] high.

Each mask is made up of 23 or 24 separate stones, exclusive of the band or fillet across the forehead.

It seems likely that the masks were arranged in groups of three, one above the other, as sufficient sculptured elements were found to make possible such a reconstruction. However, time permitted only the replacement of two masks in each vertical panel. In all, 13 masks were replaced this season. It is interesting to note that in the central mask-panels on the northern and southern sides of the temple, the curling nose elements are small and relatively insignificant as compared with those of the corner masks which are silhouetted against the sky as if this greater emphasis on the corner masks was intentional.

Only one example of a re-used stone in these masks was noted. It is the left eye of the lowest mask in the center of the southern side. This stone is also carved on the reverse side.

The masks were elaborately painted in red, green, yellow and blue. The lowest masks of the northern and southern sides still retain considerable paint. The mouth was painted red; the lips yellow or green; the ears, green, to represent jade; and the ear-plugs, red. The ornaments above and below the ears are red, blue or yellow; the eyes red, yellow or green, or combinations of any two of these three colors. The eyebrows are green or blue. The head band, which represents three or four ribbons, was painted blue, green, red and yellow. The masks show small individual differences and seem to follow a style developed between 980 and 1200 AD, that is, before the Toltec Conquest.

The other sculptured motif of the lower zone of the Temple of the Warriors represents the serpent-bird, which is a reciprocal concept of the feathered serpent. These serpent-bird panels have bird feet and bodies with great plumes rising to the top of the panel and gracefully sweeping to the sides, forming a complete arc and falling down the sides to the base of the panel. Projecting from the center of this balanced design of feathers is a serpent's head in full relief. The tongue of the serpent is bifurcated and hangs downward, being produced by two separate stones tenoned into the wall below the serpent head. The open jaws of the serpent hold a human head.

The serpent-bird panels average 6 feet 5 inches [2 m] in height and 6 feet [1.8 m] in width, and begin at a height of 1 foot 7 inches [48 cm] above the lower cornice. They show but slight variation in their individual treatment.

The corresponding serpent heads were found for all six panels, which were repaired, and three of the human heads. Casts in white cement of one of the original human heads

were made as substitutes for the three missing ones. In only one case were the two stones forming the bifurcated tongue found entire. The serpent-bird panels are composed of from 27 to 30 stones, exclusive of the two stones for the serpent jaws, the human head and the bifurcated tongue. The stones for the panels on the west (front) side were all found. This may be due to the fact that the very wide terrace on this side of the pyramid prevented them from falling down the talus and thus being broken or destroyed.

An interesting and curious fact in relation to the western mask on the southern side is that three of the sculptured stones belonging to it were found some 250 yards [228.6 m] northeast of the pyramid, where they had been piled with other sculptured and plain stones around the rim of a dead cenote.

The sculptured panels of the northern and southern sides retain the most paint. The background is red with red and green feathers. The body of the bird surrounding the head is green with red trimmings. Some traces of red paint were noted on the serpent jaws. The human heads show numbers of coats of plaster, each of which has a layer of paint, either red or yellow or a combination of the two.

This completes the decoration on the lower zone. The vertical central of the medial three member cornice was in the form of two serpents. Two heads to accompany the bodies of these serpents were the corners of the building, and two tails were found in the debris of the central portion both the northern and southern sides.

The character of the sculptural motif of the upper zone, that is, above the three member cornice, has not yet been worked out. Sculptured elements belonging to this motif were found on all but the western side. Lack of time prevented close examination of this material, so that nothing definite may yet be said concerning its nature. However, it is quite probable that with careful study it may be possible to assemble these elements in their original positions.

Notable results have been achieved by Mrs. Ann A. Morris, another of the staff artists, in reassembling the fragments of the mural paintings in the Temple of the Warriors. She has succeeded in fitting together most of the pieces, which came from Area 31,¹ some 57 in all, thus recovering the greater part of the original design. A coastal scene is represented here. Canoes, carrying two warriors each, are being paddled along the shore, upon which stands a village. The water abounds in fish of several kinds, as well as snails, crabs and lobsters. On land a number of people are engaged in various occupations: a woman is grinding corn or

washing, another watches a boiling pot, a man carries some burden on his back, another is fighting, others are walking between thatched houses or under trees; the whole constituting an intimate picture of life in some ancient coastal village.

Another equally remarkable scene is presented on an assemblage of six fragments from Area 24. Here the subject is a human sacrifice. The sacrificial victim lies upon a convex altar, made by a curl the body of a feathered serpent, his breast curving upward, and his arms and legs grasped by two attendant priests. A tall priest stands behind the altar with upraised knife ready to strike the fatal blow, which behind there rises in graceful curls the body of the feathered rattle-snake with opened mouth and darting bifurcated tongue, in whose honor, it may well be, this sacrifice is about to be consummated. The sacrifice takes place before a temple, some architectural details of which, doorway, cornice elements, etc., may be distinguished; a strikingly life-like presentation of what must have been an all too common sight at Chichén Itzá during the Toltec period.

In her report covering the work of restoring the original designs, Mrs. Morris gives interesting facts concerning the methods she employed. In speaking of the restoration of the village scene she writes:

The *modus operandi* in restoring this design was as follows: four representations were made of the area. First, each stone bearing painted plaster was reproduced in water color; second, an ink drawing on a scale of 1 to 5 was made of the outlines of the individual stones arranged as a whole; third, a restoration of the missing parts was then attempted in another ink drawing; and fourth, the preceding was painted, in accordance with the colors actually found in the first reproduction.

Justification of the restoration thus secured is based upon the following points. The parts restored are in no case derived entirely from the imagination; they are invariably exact representations of other similar elements found in adjacent areas. For example, the prows of the war canoes are all restored on the pattern of one clearly represented in the next area. The trees are completed in symmetrical fashion. A snail emerging from its shell was thus associated through the finding of another complete representation of such a figure, while the restored anatomical parts of humans and fishes are direct copies of others to be found in the same area.

The arrangement of the individual stones in the composition as a whole was effected in the following manner: First, painted reproductions were made on sections of paper of exactly the same sizes as the stones themselves, which

proved of invaluable aid in the final moving and adjustments to place.

Where the parts to be joined were clearly indicated on two adjacent stones, no difficulty was encountered, but, where arbitrary placement was necessary the following characteristics of the composition served as a general guide. The shore line indicated on a large scale the placing of the stones, since at this horizontal line the background changes color from red to blue. A second useful working principle was found to be the very constant habit of the ancient Maya mason of laying his wall up by tiers of even height. With the infinite variety in the size and shape of the stones encountered, the problem receives direct aid from this source. A slight increase in scale of the figure drawing from bottom to top was a third source of aid in the correct assemblage of the design elements. When all of these points were borne in mind and simultaneously adjusted, the correctness of the assemblage ceased very largely to be a matter of conjecture. Indeed, there were only two stones which were placed adjacent to unrestored gaps for which absolute proof of their original positions can not be given.

Regarding her restoration of the sacrificial scene she says:

The greatest gap in this restoration occurs where the face of the sacrificial priest should have been. The face which has been inserted in its place is the replica of the face of another priest from the same area. The correctness of the association of these six stones is evident from the fragmentary lines on the different stones which join with each other, the single obscure place being the decorated top of the temple; but even this is seen to tie in with a fragment of the same carved element found between the tooth and speech-scroll of the snake.

This scene depicts the body of a human victim stretched over a sacrificial altar. Usually these sacrificial altars are represented as convex blocks of stone, but in the present case the coil of a great serpent body serves this end, no doubt symbolically. The feathered serpent itself looms over the whole group in barbaric magnificence, the patron of the bloody rite about to be consummated.

Two priests painted black from head to foot, except for their hands, grip the ankles and wrists of the victim to be sacrificed. The officiating priest, also painted black, stands over the prostrate victim with upraised knife. This knife is identical in color and shape with one to be found in the collection of Señor Don Rafael de Regil of Mérida, Yucatán.

All three priests are clothed in blue garments. The sacrifice takes place on a low stone terrace in front of a temple with a sculptured cornice. The whole group becomes of even greater interest when one reads the descriptions of identical ceremonies described by the first Spanish invaders of Yucatán. Doubtless it will be possible to make other similar restorations of other areas from fragments found in the Temple of the Warriors, and thus, in part at least, to recover some small remnant of the beautiful and rich designs formerly painted upon its interior walls.

In connection with the copying of these mural paintings a correlative study of the early Spanish and Maya writers is being made, which has already given much corroborative data as to ancient Maya dress, weapons, and customs.

The sculptured and richly painted panels representing two human figures, which were carved upon the door jambs of the earlier temple buried in the northwest corner of the pyramid supporting the Temple of the Warriors, were copied in color as soon as they were uncovered, since experience has shown that, after exposure to the air, the pigments begin to fade immediately and lose their former brilliance.

THE CARACOL

Through the generosity of Mrs. Frederick Guest of New York it was possible to continue excavations at the Caracol (Station 5) during the current season. This structure is one of the only three round buildings known in the whole Maya area, and has the added interest of having been constructed primarily as an observatory [Chapter 38.6 this volume].

The work of repair was carried forward under the immediate direction of J.E.S. Thompson, assistant archaeologist, who began by removing the loose stone from the upper terrace and clearing the debris between the stairway and the front of the building in order that the masons might begin relaying the fallen parts. Mr. Thompson, in reporting the results accomplished, says:

Inside the outer corridor of the tower, excavation was carried round nearly to the south doorway. In the course of this work, the fact came to light that there is a step up in each of the four doorways from the outer corridor or into the inner one. Remains of paintings were noted on the inner wall of the outer corridor, and the plaster floor had been painted a rich Prussian blue.

Just under the lintel of the south doorway was found an interesting figurine of a jaguar, or

cat, with lolling tongue, made of pottery; although this had been broken by falling stones, most of the fragments were recovered and assembled. The figurine is hollow and is about a foot long and 6 inches [45.7 cm] high.

Excavations were continued to the north of the west doorway within the outer corridor as far round as the north doorway, where work was brought to a close for the season. This leaves the outer corridor about half excavated, that is, from the south doorway around past the west doorway to the north doorway; and the exterior wall the same.

In addition to the excavations described above, the double stairway leading to the upper terrace was put in a state of repair. This stairway, although in much better condition than the stairway of the lower terrace was nevertheless, in such poor condition that, left as it was, it would have speedily disintegrated, detracting greatly from the appearance of the building.

Flanking it are a few massive blocks, all that remain of what must once have been an impressive double serpent balustrade. It was hoped the missing elements of this balustrade might have slipped off and been buried in the debris on the flanks of the stairway; and it was therefore decided to clean these areas in an attempt to recover the missing pieces. None was recovered, however, although many other objects of interest were found. Each side of the stairway was excavated to the northwest and southwest corners, respectively, of the upper terrace.

The cut stone platform projecting between the two upper sections of this stairway was also cleared. Here formerly stood a dated stela and a large disk-shaped stone with a long tenon, both of which are now in the Historical and Archaeological Museum at Mérida. Buried in the floor of this platform stands a small round column, but it is apparent that it was merely part of the fill, as it is surrounded with the characteristic mixture of stone and mortar of which every Maya fill is made.

Through the discovery of a sculptured stone presenting a serpent's head with a band of hieroglyphs attached thereto, the problem of the puzzling sculptured elements found at the Caracol last year and this, with similar hieroglyphs on them, was partially solved. It was evident from the arrangement of the plain borders on the block found this season, that they had all been parts of a serpent with a hieroglyphic body, which had wandered in right-angle turns across the upper part of the tower. It is hoped that when the Caracol shall have been completely excavated, and all the parts of this design recovered, that it may be possible to rearrange this inscription in its original order.

THE GROUP OF THE INITIAL SERIES

Data of a somewhat surprising nature seems to have resulted from the excavations under G. C. Vaillant, assistant archaeologist, at the Group of the Initial Series (Station 13), in Old Chichén Itzá, which appears to be almost, if not entirely, a unit of Toltec origin.

A test trench sunk into the western side of the pyramid supporting the Temple of the Initial Series revealed an earlier temple, built into or covered by the later construction. This earlier temple-itself would appear to have been of Toltec origin, judging by its sloping exterior base, practically a diagnostic feature and, if so, it is to be doubted whether any of the structures of this group go back earlier than the Toltec Conquest.

Excavations at several points in the general terrace supporting the different structures of this group indicate clearly enough that the Temple of the Phalli is its oldest unit. What is not yet certain, however, is whether or not this oldest building precedes or antedates the Toltec Conquest, although the remaining structures are pretty surely all of Toltecan origin.

The Atlantean column, another diagnostic characteristic of the Toltec Period, is found more extensively at this group than at any other in the entire city, three of the four structures at Chichén Itzá, thus far found presenting this feature, occurring here.

At the beginning of the present year only two structures having the Atlantean column were known—the Temple of the Initial Series at this group and a small temple just south of the High Priest's Grave (Station 11). During the course of Mr. Vaillant's excavations at Station 13 a new temple at the southeastern edge of the group was found presenting this feature. The two heroic sized Atlantean columns, which divided its triple doorway, were composed of sections like those in the Temple of the Initial Series, which they very closely resemble in size, style and treatment. The several sections were scattered about on the ground, some sections being badly shattered. Extremely careful excavation, coupled with the immediate replacement of the different fragments recovered, made possible the practically complete repair of the shattered elements and the re-erection of these two handsome examples of the Atlantean column.

The other example of this feature was found in the Temple of the Little Heads, also at Station 13. In this case the two Atlantean columns (also made in sections) were not in the façade, but supported the double arched ceiling of the single chamber.

The long-missing second sections of the two Atlantean columns in the Temple of the Initial Series, which presented the part of the figures between the neck and the waistline, were found this season through the vigilance of the native mayordomo, Juan Olalde,

and restored to their original positions. These sections fit beautifully and very considerably enhance the dignity of the temple doorway, which without them had appeared squat and ineffectual. They were found at the base of the pyramid, one on the northern and the other on the southern side.

Extensive excavations south of the Temple of the Phalli brought to light a welter of walls, colonnades, courts, etc., most of them apparently of late construction, built without conformance to any well-defined plan of grouping. Before the final time relationships between these several structures can be worked out, further investigation and study will be necessary.

The trenches in this complex yielded a great number of have been classified and studied by Mr. Vaillant, as gave all the ceramic remains, fragmentary as well as entire, recovered during the past three seasons. In the detailed report of his studies of the ceramics of Vaillant says, in part:

The method of nomenclature here used is frankly tentative. The two most characteristic points about a vessel or potsherd are its color and provenience. Shape, though important, is difficult of precise definition in a fragment. The titles used below are calculated to describe the most striking point of the ware without being so bold as to confound a ware of similar hue with one of different composition. When possible, as in Plumbate Ware, general usage in nomenclature has been followed.

The type of pottery most commonly found is Decorated Slate Ware, which is built from a coarse, heavily tempered paste that takes a pink to a red shade under fire. Over a vessel the potter commonly ran a wash, a slate grey in color for the most part, but there are shades that vary from a fish-belly white to a creamy yellow. Sometimes the slip would be applied too thin, and the red of the base clay would be left pure, or possibly with a grey sweat, greasy to touch, upon it. The main forms are ollas with broad shoulders, tapering to a flat base, having handles vertical or horizontal, commonly disposed in pairs. Less often one finds a globular bottle form, usually with a flat base. Also this ware appears as large bowls or *cajetas*, with a wide mouth usually a little smaller than the greatest diameter which occurs at the bottom of the rim. Their bottoms are flat and they have handles. The decoration of this ware is simple and labor-saving. The handful of fibers, or of whatever the brush was made, makes a blot, in ollas near the junction of the shoulders to the neck, in *cajetas* at the edge of the lip, and the paint is allowed to run down the side subject to some rough guidance. Very occasionally in ollas, but never in *cajetas*, a design, like a series of SS laid horizontally, is run around the neck above

the vertical stripes. Ollas, naturally, are only decorated on the outside; cajetas, on the inside as well. On vessels which have the slip burned away by too much fire, the decorative paint remains in white streaks.

The second great ceramic group at Chichén Itzá has been called Porous Grey Ware. The basal paste is grey in color, ill-kneaded, without much tempering. For utilitarian needs small bottles and ollas were made, often with no slip, but sometimes having a thin wash of the same material run over them.

A much commoner variant of this ware, which well may have been used for cooking, in distinction to the employment of Decorated Slate Ware for storage or for eating, was Striated Porous Grey Ware, comprising small ollas without a slip, with thin walls shallowly furrowed by raking with some toothed instrument.

A third variant found some years ago in the Sacred Cenote by Mr. Edward H. Thompson, but rarely obtaining elsewhere, has strips of clay filleted on to small bottles, while finger-pinching their bands gives a ribbon-like effect.

A fourth variant of this group represents a transition between Porous Grey Ware and Decorated Slate, the paste being of the former and the slip and paint of the latter category. It is very rare.

Found almost without exception in the cenote are small bowls with round feet, perforated but not truly, hollow, or else with solid teats as supports. The vessels received no slip, but directly a ball of copal incense was molded and set in them, the whole was covered with a blue stucco. A variant of this practice is painting, in white, blue and black, such a pot after it has been fired. At times, but most infrequently, the feet may be modeled into the faces of men or animals. This practice extends to the red-lacquered Porous Gray Ware (Red Lacquer Ware), but due to the habit of leaving the feet unslipped in this style it is hard to detect.

A third group, distinct if not numerous, is Polished Red Ware. On a paste burning red, good in kneading, tempering and firing, a slip of the same clay is run and burnished. While the common form is the olla, tripod bowls, some what better made, obtain occasionally. One or two examples exist of deep, flat-bottom bowls. Somewhat commoner axe vases, more or less cylindrical, set on an annular foot. The usual decoration is a simple horizontal groove or series of grooves around the neck. Examples exist of complicated graving in the form of a braid or of gadroons over the body of the pot. Possible trade pieces are deeply carved fragments representing a combination between floral patterns and those of abstract design. Half

of a bowl exists with a band of carved flowers around the lip. Another suggestion that this carved ware may be an importation is that it does not exhibit the regularity of shade of the common brand.

Actually the finest ware, with the exception of Plumbate, is Polished Orange. Here we have a truly excellent paste, kneaded with cunning and tempered with sophistication. A slip, generally orange but occasionally burning red, presents a glossy surface. Decoration comprises painting simple rectilinear patterns in black on the exterior of vases, on bowls, or on flat bottom tripod bowls. In several instances, around the exterior of the wall of the pot, highly conventionalized birds are painted in deft free-hand. The forms are tear-shaped ollas set on cascabel feet, or bowls with low annular bases, or dishes with a flat floor and erect concave walls resting on legs like hollow truncated cones. One sometimes finds incision through a broad black stripe, or again incision direct into the paste. More rare is a white slip with incisions in broken-down glyph patterns; indeed such vessels have a very foreign look.

The ceramic art is not confined, obviously, to the mere fabrication of pottery vessels. At several points excavated by the Institution, spindle whorls of pottery came to light. At Station 13 many of these were graved with designs of birds with out-stretched wings, and this type also is found elsewhere. From Station 13 also came pottery pestles, with punched grinding surfaces and often effigy heads, for use probably with grating bowls. The material seems to be the same as the basal paste of Decorated Slate Ware. From the same locality appeared a carved seal for stamping cloth. A tray, or olla cover, and fragments of another came also from the same station. There occur tiny model pots, individually or in connection with a "late" incensario. Worked sherds, for potters' tools or for gaming, according to shape, are found in small numbers. From Station 5, the Caracol, we have an example of a couchant jaguar, some 7 inches [17.8 cm] in length. This object is the only known example of the figurine at Chichén Itzá and it was found in late debris. On the other hand, the figurine is a very common ceramic type among the Maya, and the Aztec, Toltec, and "Archaic" peoples of Mexico.

Chichén Itzá ceramics are not Mexican, nor, on the other hand, are they Mayan, but more Yucatecan from force of composition. In shapes, particularly in the art pottery, clear differences exist between Chichén Itzá wares and those from other Mayan sites. Also two wares occur, the polished orange and incised, white on red, which, although they are not Mayan and do not occur frequently enough to be called Chichén

Itzá, need to be anchored. Further investigation, particularly with reference to single occupation buildings, ought to produce more information on the chronological sequence of styles. The best procedure, now, is an external attack, based on a regional segregation of wares.

Four units at the Group of the Initial Series were repaired during the current year, as follows: 1. The gateway of the group with adjoining sections of the low parapet, which was built around the edge of the general terrace; 2. The Temple of the Initial Series, and the earlier temple covered by its substructure; 3. The Temple of the Little Heads; and, 4. The Temple of the Atlantean Columns.

The excavations at this station during 1926 may be said to have established two general points: First, that this group, practically in its entirety (with the single possible exception of the Temple of the Phalli, by no means certain) dates from the Toltec Period, 1191 to 1448 AD; and second, that even within this short period of time, two and a half centuries, considerable changes, alterations, additions, extensions, etc., had been made. So extensive indeed are these changes that building operations here would almost seem to have been continuous throughout the Toltec Period.

NOTES

1. The walls of the Temple of the Warriors both exterior and interior were divided into areas during excavation and to facilitate reassemblage and subsequent study all painted or sculptured fragments were marked with the number of the area in which they were found.

EARL H. MORRIS

Report on the Excavation of the Temple of the Warriors and the Northwest Colonnade (Stations 4 and 10)

YB 25:282–286, 1926

During 1926 excavations at the northwest corner of the Court of the Columns, that is, the Temple of the Warriors, were centered upon the clearing of the Northwest Colonnade (Station 10). The latter structure is the long columned hall which flanks the entire western

side or front of the Temple of the Warriors' pyramid and continues both north and south there from. In 1925 this building was transected by a drift three inter-columnar spaces in width, driven for the purpose of laying bare the foot of the stairway leading to the portal of the Temple of the Warriors. In 1926 digging was begun at the right side of this cut and was carried southward until the limits of the building had been passed and two transverse rows of circular columns, constituting the north end of the very long edifice which forms the western range of the Court of the Thousand Columns, had been laid bare.

The north half of the Northwest Colonnade was excavated in two levels. First, considering the general surface of the mound as a base, the talus, triangular in cross-section and lying against the pyramid north of the stairway was removed. This digging yielded the faced stones which once comprised the third and fourth battered elements of the contiguous portion of the pyramid; the carved blocks of the sculptured band which was situated between the two; and the huge serpent's head originally tenoned in at the top of the northern balustrade of the temple stairway. In this area, just as excavation reached the undisintegrated hearting of the pyramid, at which point under ordinary circumstances it would have terminated, it was discovered that, encased within the rubble of the hearting, there exist the remains of what was once a magnificent serpent-columned temple, part of which had been torn down and the remainder buried during the construction of the pyramid destined to support the later Temple of the Warriors. This underlying temple will be briefly described on a subsequent page.

By the close of the field season the lower level north of the stairway had been cleared of debris. There remain only a few cubic yards of vegetable earth and fallen wall-stones covering the three steps, which lead from the major terrace to the platform upon which the building stands, to be removed before the excavation of the Northwest Colonnade will be completed.

As a preliminary to a description of the repair work, it may be stated that the field staff considers it advisable not to develop the eastern, or rear, face of the pyramid, leaving that exposure more or less as it was found as a control section for future investigators, and as an example of conditions previous to excavation.

The fallen elements of the south face of the great pyramid were replaced to the limit of positive knowledge of the original treatment; that is, up to and including the 6 inch [15.2 cm] vertical cornice surmounting the fourth, or uppermost, sloping element. The distance thence to the top of the pyramid is just enough to allow for the completion of the fourth multiple zone in the same style as the other three; or definitely expressed, to allow for a 26 to 28 inch [66–71 cm] vertical band

with an ultimate 6 inch [15.2 cm] vertical cornice. Certain it seems that the fourth zone was completed in major pattern like the ones beneath. However, a reassemblage of the sculptured stones from the south side permitted the replacement of three sculptured bands, which sections found in place prove to have been the lower three, and left no residue to represent a fourth. Hence, obviously, the latter was not sculptured. Moreover, specially shaped corner stones were found in sufficient number to replace all elements up to and including the cornice above the fourth battered element; but not one at any corner of the pyramid, to prove the form of the termination of the two upper members of the fourth multiple zone. While there can be little doubt that this zone deviated in pattern from the others, presumably having been finished a band of plain faced instead of sculptured stone, the proof of this point is inferential rather than concrete. Therefore, a restoration was not made.

When the repair of the north face of the pyramid had been practically three-fourths completed, the discovery of the previously mentioned buried temple imposed the necessity of deferring the remainder of this work until another season. Nor could the north half of the western face be replaced until this earlier structure has been explored to the extent that its condition and the discoveries to be made within it dictate. Nearly all of the southern half of the western face was repaired during 1925. However, there remained for treatment the south margin, of the temple stairway. As stated in the report for 1925 [Chapter 38.3 this volume], this stairway was approached through the three central portals of the Northwest Colonnade. It led upward through a well, formed by a modified vault of the colonnade, emerging from the roof, thereof at about two-thirds the height of the pyramid. Beginning at the floor of the lower hall the stair is bordered by balustrades, 45 inches [114.3 cm] in width, each graven in low relief with the rattles and first body whorls of a feathered serpent. The portions found *in situ* extended from the inner foot of the third row of columns, counting from the west, to the line of the outer face of the fourth row, at which point they were interrupted by the vertical faces of the wall closing the ends of the fourth, or, innermost, vault and the inner half of the third vault, these being the parts of the roof transected by the stair. Among the surface debris which slid down from above were found blocks bearing the same low relief carving of the serpent whorls, and far down upon the stair was a very large serpent's head, its rough tenon indicating that it had been set into masonry in a horizontal position. Obviously where the stairway emerged from the roof, the balustrades began again. The rattles being at the foot, necessarily the head must have been at the top of the balustrade. Precedent for the plac-

ing of the head in this position was provided by the small serpent's head found *in situ* in the north ramp overlying the steps, giving access to the Northwest Colonnade in front of the central third of the great stairway. This head is set into a vertical collar, the crest of the upper jaw coming flush with the brink of the terrace.

In order to fix the length of the upper section of balustrade it was necessary to determine the roof level of the Northwest Colonnade. A minimum height was indicated by that portion of the third sculptured band lying south of the stair. On the north and south sides of the pyramid, this same band had been plentifully painted. Not a vestige of paint, however, could be found upon any stone included in this band where it extended across the west face of the pyramid. Hence, it was evident that the carving had been hidden from view before color was applied elsewhere. The blocks forming the edges of the balustrade were laid out so that the carving conformed in pattern to the serpent curves in place at the bottom of the stairway. One margin proved to be continuous and was assumed to be complete. Considering the top of the third sculptured band of the pyramid to have been the roof level of the Northwest Colonnade and giving the collar surrounding the serpent's head the same relative proportions as the small one found in place, the diagonal line from the assumed roof plane to the lower edge of the collar, and the supposedly complete row of balustrade margins lacked but one inch [2.5 cm] of being the same length. Hence it was assumed that the original alignment had been determined, and the stones were reset to conform thereto.

The Northwest Colonnade demanded a relatively small amount of repair of which practically half was accomplished by the end of the season. Repair upon the Temple of the Warriors itself was under the immediate supervision of Karl Rupprecht.

Excavations have revealed the Northwest Colonnade to be a structure 148 feet [45.1 m] in length and 48 feet [14.6 m] in width, essentially conforming to the dominant pattern of the columned halls so plentifully found at Chichén Itzá. Such variations as it exhibits consist of the presence of, or omission of, certain features occasioned by its adjustment to contiguous structures. For instance, the south end wall and the anta which normally should have extended northward therefrom are missing, this because the Northwest Colonnade and the structure comprising the western range of the Group of the Thousand Columns, although built at different times, were not separated from each other by a partition wall. The absence of this southern anta makes the Northwest Colonnade asymmetrical, there being eight intercolumnar spaces north of the temple stairway and seven southward thereof. Thus the hall contains, including the two resting upon

the stairway, 63 columns. There are 16 columns in each of the three eastern tiers and 15 in the front or western one, the northern anta having served the function of the terminal member, of this row. These columns are rectangular, 8 feet 9 inches [2.7 m] in average height. Those of the forward row are 25 [63.5 cm] by 29.5 inches [74.9 cm] in cross-section and the others 20.5 [52.1 cm] by 27 inches [68.6 cm]. The average intercolumnar space is 8 feet 2 inches [2.5 m]. All except the two on the stairway axe sculptured in the customary fashion; all four sides of each bearing a warrior or priest standing upon a serpent-bird-human panel, and surmounted by a sundisk, from the nether side of which issues a crouching human form. All of the columns, as well as the entire interior of the building, have been painted in brilliant hues.

A bench 5 feet 6 inches [1.9 m] in width and 2 feet [61 cm] in height, with a 6 inch [15.2 cm] vertical cornice over jutting 2 inches [5.1 cm], is continuous along the back wall except for that portion blocked by the stairway. Resting upon the bench and leaning against the rear wall is an inclined element 2 feet in height, like the one described in the report for 1924, found in the Northeast Colonnade [Chapter 38.3 this volume].

Enclosing the first two columns in the inner row, south of the stairway there is a superlatively fine dais, 16 feet 5.5 inches [5 m] long, 13 feet 2 inches [4 m] wide and 2 feet 9.5 inches [85 cm] high. The battered basal zone is sculptured with a procession of richly adorned, human figures, and upon the 8 inch [20 cm], vertical cornice are graven the sinuous curves of plumed serpents. All of the sculpture had been overlaid with pigment, which, when first uncovered, retained almost its original brilliance. Life-size copies in oil were made very soon after excavation by Jean Charlot.

This dais was not included in the original plan of the hall as proved by the fact that the carving upon the columns which it encloses continues to the fact that the carving upon the columns which it encloses continues to the floor level of the chamber. Then, as an afterthought, a stairway 8 feet 7 inches [2.6 m] wide was built against the front of the dais. It was very poorly constructed, but had been plastered with many coats of white. At the time of its erection a white finish was applied to the floor upon the dais to the front of the building. In the line of the east and west axis of the dais to the front of the building. In the line of the east and west axis of the dais, 10 feet [3.1 m] forward of it, there was set up at the same time a block of stone of truncated-pyramidal form, 1 foot 4 inches [40.6 cm] long, 1 foot 2 inches [35.6 cm] wide, and 1 foot 3 inches [38.1 cm] high. This may well have been an altar in its true sense; that is, a place of sacrifice, the object over which victims were bent and their breasts drawn taut to offer less resistance to the sacrificial blade.

There is another dais in the north half of the hall, like the former, of secondary construction, but disappointing in comparison. It is vertically walled, 11 feet 6 inches [3.7 m] north and south, 9 feet 1 inch [2.8 m] wide, and 2 feet 6 inches [76.2 cm] high, enclosing not the first and second columns from the stairway, but instead the second and third. The basal zone was unsculptured and painted red. The 6 inch [41 cm] vertical cornice contains a few sculptured stones, evidently reused. These had been plastered over so that the carving was hidden.

The north, south and west façades of the Northwest Colonnade bore much sculpture. There were the inevitable grotesque masks; heteromorphic panels, or shields, representing the same figure found on the bases of all the columns; and certain other panels containing as a central element a human head with the beak of a bird. There were also tenoned into the frontal façade four human figures carved in the full round, seated Buddha fashion, each wearing a stone mask as a head-dress. One of the two recovered complete is, in the opinion of the writer, the finest piece of sculpture thus far found at Chichén Itzá. A full reassemblage of the sculptured elements could not be completed during the season of 1926.

A considerable portion of the sculptured material from the south half of the front wall had been removed long since, but subsequent to the fall of the building. This stone robbing extended even to a number of the blocks of the southern members of the front row of columns. Conical pits dug into the slope of the mound to permit their removal, and afterward filled by the gradual accumulation of vegetable mold, were plainly visible during the course of excavation.

The partly dismantled temple buried in the northwest corner of the pyramid of the Temple of the Warriors, once extended a considerable distance northward thereof, and possibly may have encroached upon the area now occupied by the Temple of the Tables. The entire north half was torn away, and the south half, both of the pyramid and surmounting temple, were encased within the larger and later pyramid. The floor level of the pre-existent temple was 17 feet 6 inches [5.3 m] below that of the Temple of the Warriors. A complete cross-section of the eastern face of the pyramid on which it stood was found during the repair of the north face of the pyramid supporting the Temple of the Warriors, but as yet this has not been laid bare sufficiently to permit its detailed description. The temple itself was a two-roomed sanctuary of the same general type as the Temple of the Tables. There was a row of four rectangular columns in the longitudinal, or north and south, axis of each chamber, and two round serpent columns formed the divisions of the westward-facing tripartite doorway. Judging from the

portions uncovered, most of the south half of the building, exclusive of the front wall, exists to the height of the columns. The three of the latter uncovered and some 8 feet of the south wall retain, the former, both their sculpture and painting, and the latter its painted decoration, in an excellent state of preservation. These elements were encased in earth to insure their protection until another field season will permit the thorough excavation and protective treatment of the buried structure.

The huge serpent's heads and tails from the portal had been rolled back into the frontal chamber in ancient times and used as elements of the masonry with which it was filled. Although somewhat broken, they retain their color in unusual brilliance, thus giving in full detail the color treatment of the serpent column. The sculptured pilasters from the door were also recovered from the fill.

The Temple of the Warriors and its included and adjacent structures offer a rich field for the determination of the chronological order in which they came into being. For instance, the round-columned hall forming the western range of the Group of the Thousand Columns once extended northward to, or almost to, the stairway, leading to the Temple of the Warriors, its floor level being traceable some two feet beneath that of the south half of the Northwest Colonnade. It now seems probable that the east-facing façade laid bare in the southwest corner of the pyramid in 1925 is the rear exposure of this building. Again, under the north half of the colonnade, there is a second floor level less than a foot [31 cm] beneath the one on which the columns stand, and others may be found at still greater depths. Thus it seems that the site of the Northwest Colonnade has been built upon at least three times. Counting the buried temple, and lastly the Temple of the Warriors itself, the total number of construction intervals amount to 5, to say nothing of the one and probably more stages of remodeling in evidence where the North Range of the Group of the Thousand Columns impinges upon the west end of the south side of the great pyramid.

The positive chronology of all these different periods of construction and their significance can not be stated at present. During the season reported upon, with a large force occupied in excavation and another in repair, there was not an opportunity for the detailed and careful work necessary for tracing out the sequence of walls and floor levels. This particular endeavor will constitute one of the principal aims of the 1927 field season. One fact of general significance, however, already seems to be indicated; namely, that the round column antedated the rectangular one, as evidenced by the presence of the ruin of a round-columned structure beneath the Northwest Colonnade, and the existence of

the buried temple with circular serpent columns beneath the Northwest Colonnade, and the existence of the buried temple with circular serpent columns beneath the Temple of the Warriors, whereas in the latter structure the homologous elements are rectangular.

38.11.

EARL H. MORRIS

Report on the Temple of the Warriors and the Northwest Colonnade (Stations 4 and 10)

YB 26:240–246, 1927

Excavation and repair work at the Temple of the Warriors and adjacent structures was carried on throughout the 1927 field season, and was practically completed by the end thereof. The Temple of the Warriors comprises three distinct elements, these being in order of relative importance: 1. The Temple of the Warriors itself, together with its pyramidal substructure; 2. The pre-existent Temple of the Chac Mool encased within this pyramid; and, 3. The Northwest Colonnade.

In the following discussion, this logical order of presentation will not be followed, but instead that indicated by the volume of work and the intricacy of the problems involved in the treatment of each of these several units.

The general features of the Northwest Colonnade were given in the *Year Book* for 1926 [Chapter 38.4]. During the current season the excavation of this structure and the repair work were completed. The latter involved the setting up of practically all of the columns in the north half of the colonnade. In the failure and collapse of this portion of the structure, the thrust was forward, and each column served like the half of a hinge, the base being the bolt upon which it turned. With synchronized movement the columns swung westward until with the final crash they lay fully extended upon the floor, or partially blocked up by heaps of masonry that came down before the fall of the main mass of the roof. With the exception of a few terminal blocks, these columns were replaceable in their entirety. The repair of the north anta, the north wall of the building, and the rear or east wall north of the Temple of the Warriors stairway, although involving the replacement of a great deal of masonry, entailed no difficult or complicated problems.

A series of pits and trenches sunk into the terrace supporting the Northwest Colonnade revealed three earlier floor levels. At a depth of 4 to 5 feet [1.2–1.5 m], closely overlying the original ground level, was a red-tinted polished lime floor which had been long exposed to the elements. Presumably this represented an early terrace level, possibly a portion of the major terrace upon which the Castillo, the Ball Court and the Group of the Thousand Columns stand. Overlying this level there is a 2.5 to 3 foot [76–91 cm] layer of large rough stones, dry laid, the interstices being cavities instead of being chinked with either earth or mortar. Above this open fill is a second red plastered lime floor which, when traced southward, proved to be a northward extension of the floor of the West Colonnade of the Group of the Thousand Columns.

This latter structure at one time continued the full length of the area now occupied by the Northwest Colonnade and then swung westward, its low frontal terrace making a right-angled turn in that direction a short distance south of the north anta of the later colonnade. At the southern end of the West Colonnade, there exists a westward pointing wing with a small pyramid at its end. This, together with the above-mentioned vestige of a possibly similar structure at the opposite original extremity of the West Colonnade, would seem to confirm the conclusion, indicated by the fact that the West Colonnade faces the Castillo, namely that the West Colonnade was planned and built with definite reference to the Castillo, some time before the plan of the Court of the Columns had been called into being.

Sunk into this second floor level directly beneath the southern member of the pair of columns in the Northwest Colonnade, which stand at the immediate foot of the stairway leading to the Temple of the Warriors, is a masonry lined pit, 4 feet 8 inches square [45 square cm] and 2 feet [61 cm] deep. The walls and floor showed the effects of long burning, and in the bottom was a layer of from 2 to 8 inches [5.1–20.3 cm] of fine white ash, evidently derived from thoroughly calcined bone. Apparently this pit is the homologue of the carnero of present day Yucatecan cemeteries in which disinterred bones are burned.

Under the south end of the Northwest Colonnade, above this second floor level, there was an uninterrupted fill containing some re-used round column drums and many wall and roof stones from dismantled structures. However, beginning at the north line of the sculptured dais just south of the Temple of the Warriors stairway and continuing westward to the frontal row of columns of the Northwest Colonnade, thence turning north and extending an indeterminable distance beyond the north end of the Northwest Colonnade, is the terrace which once supported a building

intermediate in age between the West and Northwest Colonnades. The floor levels of these two are only 4 to 8 inches [10.2–20.3 cm] apart. Three masonry steps led to this terrace across its southern end, and a similar stairway gave access to this level across a considerable portion of the front or western exposure; ramps bordered the ends of this stairway, beyond which, both north and south, the face of the terrace continued as a slightly battered red plastered wall.

The front of the terrace of the Northwest Colonnade was subjected to at least one modification. Its original boundary was a slightly battered wall 8 feet [2.4 m] forward, that is, westward of the building. The three-step stairway pertaining to this facing is very narrow, having only the width of the intercolumnar space lying directly in front of the center of the stairway leading to the Temple of the Warriors.

Later this terrace was widened 4 feet [1.2 m] and faced with a three-step stairway extending the full length of the colonnade, the one partially visible before excavations were begun.

In the repair work undertaken after the excavation of the Northwest Colonnade, masonry-lined trenches were provided to leave permanently visible all of the salient subfloor features above described.

The Temple of the Warriors demanded no further excavation, but considerable repair work was necessary before the building could be considered completed. This consisted of re-erecting the rear wall up to and including the lower cornice; realigning the slab flooring of the altar; replacing the elements of the three mask panels at the northeast corner; adding an upper mask panel to the tiers situated respectively at the other three corners, at the centers of the north and south façades, and at either side of the portal; and lastly, the replacement of the nether member of the medial cornice across the entire front except for the space above the doorway. As in previous years the replacement of all sculptured stones was under the supervision of Karl Rupprecht.

The north balustrade of the Temple of the Warriors stairway was raised to duplicate the southern one, described in the 1926 report. Also the facing of the northwest corner of the pyramid was carried up after the general plan followed last year in connection with the southwest corner. This portion offered greater complications, however, than those formerly dealt with, because of the Temple of the Chac Mool included within this angle. In order to leave this earlier building accessible, it was necessary to raise a vertical wall as the inner face of the pyramid shell, instead of building the successive elements against the hearting of the mound. The veneer of the pyramid on the three sides on which it was proposed to restore it, namely the south, west and north, is completed to the limit that positive knowledge

and existing conditions permit. The only gap left is at the center of the north side where a vertical section of the rind of the pyramid is absent. The upper part of this was not replaced, and the lower part was torn away to expose a complete cross-section of the substructure of the Temple of the Chac Mool, which will be described below.

As stated in the 1926 report [Chapter 38.4], definite knowledge as to the finish of the two uppermost members of the fourth multiple zone of the pyramid could not be obtained, hence no restoration was attempted. In order to protect the margin of the terrace from erosion, however, a backing of rough masonry was raised to the height of the missing members, but set back from the line thereof the thickness of the course of smooth stone with which inevitably it must have been faced. The only departure from this treatment was at the western end of the north face, where windows were left in this band to admit light to the enclosed Temple of the Chac Mool.

Many of the essential features of the Temple of the Chac Mool were given in the report for 1926.¹ The work of the present season reveals this temple to be an example of one of the two predominant types of column-supported structures found at Chichén Itzá. Other examples of this same type, which may be called Type 1, are the Temple of the Warriors, the Temple of the Tables and the principal temple on the east side of the Court of the Columns. The salient characteristics of Type 2 are exemplified by the Northeast, the Northwest, the North and West Colonnades of the Group of the Thousand Columns. The Atlantean figure altar is an accompaniment of the first type and the solidly filled, battered walled altar of the second.

The Temple of the Chac Mool was a two-chambered building, facing west 56 feet 10 inches [17.3 m] in length from north to south and 47 feet 2 inches [14.4 m] in width. Like the Temple of the Warriors it possessed a tri-partite portal, the divisions thereof being serpent columns, round, however, instead of rectangular in cross-section. The frontal hall, 50 feet 4 inches [15.3 m] long and 18 feet 7 inches [5.6 m] wide, had along its longitudinal axis a row of four sculptured columns. Directly back of the central doorway of the main portal, there was a doorway 6 feet 7.5 inches [2 m] wide and 8 feet 8 inches [2.6 m] high, with sculptured jambs and pilasters, piercing the partition wall and giving access to the inner sanctuary. This eastern or rear chamber was of practically the same size and general character as the western hall, except that it formerly had had an altar at the center of the back wall, and a bench along the north and south walls and the adjoining parts of the east wall, all of which had been removed, when this temple was filled in.

The exact dimensions of the substructure of the Temple of the Chac Mool are not ascertainable. However, a cross-section of its rear face was obtained. This exposure consists of four elements, no two of them being of the same height, nor even possessing common features. Thus the basal element is entirely plain; the second has a recessed panel at the bottom and a single vertical cornice near the top; the third a recessed upper panel and a two member cornice; and the fourth, no recessed panel, but a two-member cornice. The substructure rises from the same level as the pyramid supporting the Temple of the Warriors and has a height of 20 feet 8 inches [6.2 m]. The rear wall of the temple sets back only 3 feet 10 inches [1.1 m] from the margin of the substructures.

In clearing away for the erection of the Temple of the Warriors pyramid, approximately the northern third of the Temple of the Chac Mool and its substructure were entirely demolished, as well as the entire fronts of each. Thus the arrangement of the approach to the building has been entirely lost. There is a possibility that the terrace described as found beneath the floor of the Northwest Colonnade and above the floor of the West Colonnade had to do with the approach to the Temple of the Chac Mool, but thus far no conclusive proof has been obtained, either for or against such a hypothesis.

Evidently the pyramid supporting the Temple of the Warriors was not originally planned to extend to the height to which it was finally carried. This may be inferred from the fact that the portion of the Temple of the Chac Mool lying within the boundaries of the pyramid was demolished to a fairly uniform level from 7 to 8 feet [2.1–2.4 m] above the floor, walls and columns alike. Then the larger pyramid was built to this height, leveled off and coated with mortar, which was troweled to the semblance of a floor. Still later another 9 feet [2.7 m] of masonry was added to its height. Surely had this been the altitude originally contemplated by the builders they would not have wasted the considerable amount of labor necessary to dismantle the walls of the lower temple and to raise new masonry of equivalent bulk to take their place. This point may possibly explain why the fourth zone of the Temple of the Warriors pyramid was not embellished with a terminal sculptured band like those possessed by the lower three. Since 9 feet [2.7 m] is practically the height of each one of these four multiple zones, and since 9 feet [2.7 m] is also the height of the apparently added increment of the pyramid, it is not unreasonable to suppose that sculptured elements were carved for the originally contemplated three bands, but not for the fourth. Then later, when it was decided to add the fourth, it had to be finished with plain faced blocks, which, in the opinion of the writer, were painted with a duplication of the devices borne in relief by the lower zones.

Little can be said concerning the exterior finish of the Temple of the Chac Mool. The base of the wall has the characteristic Toltec batter, surmounted by the customary single member cornice. The stub of the vertical face extending thence upward, wherever examined, gave no evidence of sculpture. However, had there been sculpture, there is more than equal likelihood that it would have occurred between the medial and upper cornices. In the last yard of fill overlying the buried temple were found numerous elements of a magnificently carved panel representing a tree in full flower with brilliantly colored birds and insects hovering over the blossoms. This panel may have belonged to the buried temple, but perhaps with equal reason may be considered as having come from some other demolished building.

The outer chamber lay beneath the terrace in front of the Temple of the Warriors, hence its excavation offered no particular difficulties. First the pyramid hearting was removed down to the previously mentioned surfaced level to which the lower temple was dismantled. As soon as the truncated south and west walls were laid bare, new masonry was raised on top of them to the height of the terrace in front of the Temple of the Warriors. Then the remaining fill was removed, the stone therefrom being used in the building of the shell of the northwest corner of the pyramid. In this fill were found seven column blocks inferred to have come from the tops of the three remaining columns in this outer chamber. There were also encountered several sculptured jamb stones and numerous fragments of the broken jaws of the two huge serpent's heads found in the front of this chamber in 1926. The most impressive find of the season, however, was a magnificent Chac Mool figure (the eleventh of this type so far found at Chichén Itzá) which reclined on its side upon the floor near the southeast corner of the room. This masterpiece of Maya sculpture had been dragged in ancient times from the terrace in front of the temple, where previously it occupied a position similar to the one in front of the Temple of the Warriors. The figure is carved from a single block of limestone, of almost flinty hardness and exemplifies the handiwork of a master craftsman. The proportions lack the grotesqueness exhibited by most Chac Mool figures and follow very closely those of a normal human body. An inverted human head with flowing hair is pendant from either side of the waist. The head of the Chac Mool itself bears a broad helmet crested with a crouching animal figure, a composite feline and reptilian conception, exquisitely wrought.

The columns and walls of the outer hall fully rewarded the expectations which had been aroused by those portions of them temporarily uncovered in 1926. Two of the columns (10 feet 3 inches [3.1 m] in height)

retained their coloration to a degree not previously observed, and gave in minute detail the vestiture of the figures depicted thereon. The wall paintings were found to be in good condition and represent the curves of the body of a great reptilian monster, done in brilliant colors.

Excavation of the inner sanctuary involved more than ordinary difficulties. The entire north anta and the western 10 feet [3.1 m] of the north wall of the Temple of the Warriors had as their foundations the loosely laid rubble with which the sanctuary had been filled. Inasmuch as these massive walls, some 125 tons in weight, had been more or less riven by settling, the first step taken was to place a concrete foundation beneath them. This was done in sections. A transverse slot was dug beneath the wall and filled with concrete, pierced at proper intervals for the reception of longitudinal steel I-beams. Then a second slot was made and similarly filled some 3 feet [91 cm] further on, so that a block of the original foundation remained between the two. When this plan had been followed out along the entire length of the mass to be undermined, the rubble between the blocks was removed and 6 inch [15.2 cm] I-beams meshing at the corner were inserted in the slots, three beneath the north and three beneath the west wall. By casting in the spaces between the first series of blocks, a solid base nearly as strong as if poured in a single operation was provided.

Subsequently a trench was dug to lay bare the tops of the south and east walls of the earlier temple. These walls were carried up by new masonry built on top of them to the necessary height, each including a massive pier of concrete, well bonded into the adjacent masonry, beneath the respective points where the boundaries of the later temple crossed those of the earlier one. Thus two dependable supports were provided. Next a narrow cut was made from the north slope of the pyramid to lay bare the top of the ancient column situated beneath the corner of the Temple of the Warriors. It was expected that the blocks to complete this column to its original height would be found in the fill. Hence the concrete pillar cast on top of it was made 2 inches [5.1 cm] smaller on each side so that slabs bearing the relief might be taken from blocks, if such were found, and applied like the sides of a box around the cement core.

When this corner anchorage had thoroughly set, a pit was sunk and a column cast halfway between the east wall of the room and the original one above mentioned, then another between the southernmost original pillar and the south wall. Thus the free portion of the Temple of the Warriors wall was brought to rest on three concrete piers. After the fill of the chamber had been removed, a fourth support was cast on top of the completed south column. This work was

carried to completion with a settling of about 1/8 inch [0.4 cm] in the walls of the Temple of the Warriors, which took place when the excavation for the first elements of the horizontal I-beam was made.

A reinforced concrete roof was then cast above the Temple of the Chac Mool and covered with earth so that no trace of the roof or of the chambers beneath it appears either from within the Temple of the Warriors or from the terrace in front of it. A door to the concealed building was provided behind the shell of the pyramid supporting the Temple of the Warriors at the northeast corner of the inner sanctuary, and as previously stated windows for light and ventilation were left in the terminal member of the west end of the shell of the pyramid.

The six columns, to judge from the sculpture upon them, each lacked three blocks to raise them to their original height. Thus 18 blocks in all were needed. Seven were found in the front hall and 11 in the inner sanctuary. The selection of blocks for the respective columns was easily accomplished and five of them were completed with no difficulty. To finish the sixth, upon which a concrete pier had already been cast, it was necessary to saw slabs from all four sides of each of the three blocks. Although the limestone was very hard and full of flint nodules, this cutting was done and the slabs cemented to their concrete core without marring the appearance of the column when finished.

Measurements of the sculptured jamb stones and pilasters, for the most part found in 1926, proved these elements to have belonged to the doorway connecting the two chambers, hence these could be restored to their original positions.

The southern two columns in the inner sanctuary are the best preserved thus far found at Chichén Itzá. The colors brilliant almost beyond belief, give in intricate detail the form and ornamentation of the dress and accoutrements of the figures depicted.

The wall paintings, except on the south wall, were not as well preserved as had been expected. However, they could be copied readily enough and were found to be the same as those upon the walls of the outer chamber, that is, the body whorls of sun serpents, each represented with a formidable head and legs armed with claws.

Unfortunately the altar had been entirely removed, its position being indicated by vestiges of a panel with a blue ground as opposed to the red background of the rest of the temple, situated at the eastern terminus of the transverse aids of the building. No elements of this altar were found in the fill. It is probable, however, that the Atlantean figures and slabs were saved and incorporated in the altar of the Temple of the Warriors, some portions of which are obviously reused in their present positions.

The bench was also torn out, but before the temple ceased to be used, as proved by the fact that the red floor was extended to the walls and plainly patched where the bench had been.

The age sequence in the Temple of the Warriors complex as now postulated is: first, a terrace in existence before any of the buildings were erected; second, the West Colonnade of the Court of the Thousand Columns; third, the structure, the floor of which lies between the floors of the West and Northwest Colonnades; fourth, the Temple of the Chac Mool; fifth, the Temple of the Warriors; and sixth, the Northwest Colonnade. However, there still exists some uncertainty as to the time relation of the last two, both of which may have been planned and built contemporaneously.

NOTES

1. In the YB report for 1925 [Chapter 38.3] this earlier construction was called simply the “buried temple.”

38.12.
JEAN CHARLOT <i>Report on the Sculptures and Paintings in the North and Northwest Colonnades (Stations 8 and 10)</i>
YB 26:246–249, 1927

The sculptures and paintings copied by Jean Charlot with the assistance of Lowell Houser during the present season were as follows:

1. Drawings and color notes of the columns of the Northwest Colonnade.
2. Drawings and color notes of the column of the Temple of the Chac Mool.
3. Paintings of the wall frescoes in the same temple.
4. Painting of the sculptured and painted dais in the North Colonnade.
5. Painting of the painted capstone found at the junction of the North and Northwest Colonnades.

The Northwest Colonnade has 59 sculptured square columns and two sculptured jambs. Of this number five of the columns have more than half of their sculptured elements missing, and one of the two sculptured jambs is entirely gone. The remaining 54 columns and the single sculptured jamb present 221

carved faces, each face divided into three sections: a standing human figure and two decorative panels, one above, the other below. All these figures were copied in black and white, and color sketches were made where it was possible to identify coloring in the original.

The technique used in cutting and joining the stones of which the column are composed, the process of carving and stuccoing, as well as the composition and use of color are the same as explained in [Chapter 38.10], in connection with the description of the column in the Temple of the Warriors and need not be repeated here.

Although the arrangement of the subject matter on the plinth is also the same as on the columns in the Temple of the Warriors, namely an upper and lower square panel enclosing a theogonic representation, and a middle rectangular panel containing a single standing human figure, many differences are to be detected both in detail and in stylistic treatment. For example the peculiar old Maya convention of a human figure seen in full front portrayed with its feet in profile pointing outward is to be found here, whereas it is wanting entirely in the Temple of the Warriors where legs and feet are invariably seen in profile, the torso presenting a slight three-quarter foreshortening.

The type of figure described last year, a warrior in elaborate array holding offensive and defensive weapons, is also found in the Northwest Colonnade, but in addition there is a new type of human figure, the column of the central rows being carved with representations of unarmed men whose hands are tightly tied by ropes encircling their wrists. Since their costumes and ornaments are as elaborate and sophisticated as those of the other figures they probably represent prisoners of high rank-chiefs and noted warriors, while the figures of the first type on the adjacent columns would appear to be their conquerors.

The details of dress and ornamentation are most abundant and diversified. The head-dresses are heavily embellished with feathers or flowers, and some are shaped to represent the features of a god. Others are like the helmets of the Aztec Eagle-knights with animal heads (serpents, tigers, quetzals) the face of the warrior appearing through the widely opened jaws. Faces themselves are often concealed by masks resembling the death's head or the God, Tlaloc, or are partly hidden behind heavy ornaments. Breast-plates are in some cases in the shape of animals (serpents and tigers) or human faces. Costume accessories such as staffs, baskets, shields, arrows and atlatsls are also fully represented.

Faces present an endless variety of expressions and types, from very youthful long robed priests with feminine features and mild postures, to aged sorcerers of threatening men who hold large thick serpents in their hands.

In places where the coloring still retains its original brilliancy, delicately painted patterns still show on the shirt, sleeves and sandals, as well as war paintings all over the body, the latter usually consisting of stripes of contrasted tones.

Even in its present incomplete condition, and especially if taken into consideration with the frescoes of the Temple of the Warriors, the figures of this colonnade present a fairly adequate picture of the characteristics of the inhabitants of Chichén Itzá during the Toltec Period, and more particularly of their military and religious clothing and accessories. A comparison between the fashions in vogue at the time when the sculptures in the Temple of the Warriors were executed, and fashions as depicted on other earlier structures, as for example in the sculptures of the undoubtedly earlier Temple of the Chac Mool, buried in the pyramid supporting the Temple of the Warriors, and also the sculptures and frescoes of the Temple of the Jaguars shows clearly a development of taste in dressing, which eventually, with the aid of other stylistic criteria, will prove of invaluable aid in assigning approximate dates to otherwise undatable buildings and sculptures.

An example of this approximate dating by means of stylistic criteria is afforded by the presence of a turban-like knee-ornament found both in the Temple of the Jaguars and in the Temple of the Chac Mool, but entirely wanting in the Temple of the Warriors. This article of apparel must have been discarded after the erection of the Temples of the Jaguars and the Chac Mool, but before the erection of the Temple of the Warriors.

Another feature peculiar to the Northwest Colonnade is the use of hieroglyphs standing above about one-fourth of the figures represented. This perhaps offers a clue to the names of the individuals portrayed and strongly suggests that at least the most characteristic of the sculptures are actual portraits. Among these hieroglyphs occur a snake, the rattle of the rattlesnake, an owl, a human bearded head, a flying bird, a human hand grinding on a metate and a seated female figure.

Three different styles of carving can be distinguished in the Northwest Colonnade. The carvings in the northern third of the colonnade are the most poorly executed. In some cases the lines are merely scratched, more as if they had been made with a sharp stone than carved with a properly shaped tool. This is particularly true of the back rows and of the eastern (back) faces of the column, which the sun never reached. The sculptors counted mainly upon contrasted colors to give the effect of high relief in the general obscurity of the northern end of the colonnade. Mediocre as is this work, however, it is in accord nevertheless with the quality of the dais toward the northern end of the colonnade,

which is vastly inferior to the beautifully sculptured and painted dais toward the southern end, where the more important rites and ceremonies would appear to have taken place.

The warriors in this northern third are depicted in different postures, but details of dress and weapons are repeated throughout with little attempt at diversification.

The middle part of the Northwest Colonnade, where the prisoners are represented, is very rich in detail and shows on the part of the artist a sincerity in representing accessories and an effort at diversification which makes it difficult to believe that he was working purely imaginatively. Indeed it would seem, that if he did not have the model actually under his eye while carving, he, at least, used preliminary sketches made from nature. The drawing is more naive than skillful, and is anatomically faulty, though it expresses character with acute penetration.

The columns of the southern third of the colonnade, though less crowded with detail than those in the other two-thirds, are more remarkable, not only for the quality of the sculpture but also for the rendering of the subject. The working of the stone is careful, and in the best-preserved parts is carried to the point of very smooth polishing. There is less close observation of nature than is shown in the other parts of the colonnade, but the freer handling of natural elements leads to a greater dignity in style.

The ornamental scrolls which are used so profusely elsewhere to conceal certain defects of composition are employed here with more discretion. Columns 58 and 59, for instance, are beautiful examples of late Maya art at Chichén Itzá and, as attempts at strongly realistic characterization, they are as successful as are the best of the Old Empire sculptures in expressing a more general religious feeling.

The group of six columns from the Temple of the Chac Mool present 24 panels which are the direct ancestors of those already described. Their most surprising stylistic characteristic is their complete indifference to anatomical proportions. The proportion of the head to the complete body, for example, varies from 1/4 to 1/8, but, even in spite of such an obvious abnormality as this, strikingly decorative effects are achieved.

As has been pointed out above, the clothing of the figures on the column in the Temple of the Chac Mool more closely resembles the clothing of figures in older temples, as for example in the Temple of the Jaguars, than it does that of the figures in the Northwest Colonnade. These earlier reliefs are more careful, even if less skilful than the later ones. Heads especially are strongly individualistic and are portrayed with a sincerity which makes beautiful in features even the ugliest. The coloring is well preserved and the strips of painted stucco between the stones axe nearly intact.

The frescoes in the two chambers of the Temple of the Chac Mool are a quadruple representation of the same motif, a highly conventionalized snake. The body is suggested by two broad blue lines enclosing successive areas of brilliant flat colors: blue, red, green, yellow and white. From the body project triangular rays, perhaps a symbol of light, forming a continuous crest along the two sides. The head, with no attempt at realistic expression, presents an open mouth between the teeth of which emerges a long reptilian tongue in the shape of a decorative double scroll. The motion of a reptile is suggested by the sinuous curves of the body. From the bottom part of each curve issue clusters of waving flower-like appendages with blue stems and yellow petals. Both head-dress and tail are adorned with similar motifs. From under the head projects a sort of stumpy leg, dressed from shoulder to elbow in a multicolor sleeve, and ending in an eagle claw.

Originally there would seem to have been eight of these serpents, symmetrically distributed, four in each chamber, and the fragments still remaining permit a rather secure restoration of the arrangement of this motif. Over the missing altar against the back wall of the sanctuary was a more minutely painted panel, of which only a trace now remains. If one may hazard a guess from the small fragment left, this consisted of human figures drawn on a small scale, performing some ceremony. The lower part of the wall in both chambers was painted a plain black but the stucco was left unpainted behind a stone bench, now destroyed. When this stone bench was removed and before the filling up of this chamber some forgotten hand had sketched in charcoal upon the white plastered wall against which the bench had stood, apparently in an accidental way, the torso, arms and head of an Atlantean figure. Another sketch of the same subject was also scratched on the painting itself.

The dais or altar found in the North Colonnade is of the same type as the one in the Northwest Colonnade described last year [Chapter 38.10 this volume]. It presents on its three carved faces a procession of 32 human figures proceeding from the two sides toward a smoking offering, probably a bowl of burning copal in the middle of the front face. The relief, which has been given only one coat of stucco, is much more apparent than the relief in the other dais, where it has been flattened by the application of numerous coats of stucco, and it therefore has a greater decorative value. This entire sculpture was copied in color in the same scale as the original.

The painted capstone found between the North and Northwest Colonnades was also copied in colors by Mr. Charlot. It presents the body of a warrior, the head and head-dress missing, in full war regalia, and is drawn on a very small scale. The stencil-like paint-

ing is in yellow, green, blue and wine-purple, and is of great delicacy; it was applied directly to the carefully smoothed white stucco, which had been in turn laid on a dressed stone. Technically it is by far the finest piece of pre-Columbian mural painting which has yet been found and compares favorably with the best pages of the codices. The upper part, which probably had a single line of hieroglyphics giving the dedicatory date, as is usually the case in these painted capstones, is most unfortunately missing.

38.13.

KARL RUPPERT

Report on the Caracol (Station 5)

YB 26:249–252, 1927

The field work at Chichén Itzá had as its goal the completion of a photographic record of all exposed low-relief carving. Although the sculpture here is probably better known than that of any other site in Yucatán, many difficult subjects had never been photographed and some of the material was inadequately recorded. It was originally estimated that somewhat over 1,000 negatives would be required; during the three-month field season approximately 1,800 negatives were made. Part way through the season the project was enlarged to include photographs of Atlantean figures, wherever they could be found.

The work was greatly facilitated by the use of a small reflex camera in conjunction with 4 by 5 inch view camera, and the use of synchronized flash lighting on subjects which did not receive the proper oblique sunlight. The negatives were developed each evening as a constant check on quality and the proper functioning of the equipment.

It soon became evident that for such problems as the reconstruction of the design on columns from loose drums and the design of sculptured panels from photographs of loose stones, the camera-to-subject distance should be kept constant in order to render objects in relative proportion. The distance maintained for close-ups was 3.5 feet [1.1 m] except where the subject was too large to be so photographed. In such cases the distance was increased to 4 feet [1.2 m] for all the close-ups made in that structure. The column drums in the South Temple of the Great Ball Court are a case in point. The distance between the camera and a row of sculptured stones was approximately 12 feet [3.7 m], as determined by a Leitz range finder.

Cylindrical column drums, because of the curvature of the sculptured surfaces, were photographed by making eight exposures at regular intervals as each drum was rolled on the ground.

It was found that dry-brushing the raised parts of the sculpture brought out details that otherwise did not appear in photographs. All the exposed carving was so prepared prior to photographing.

Scaffolding was built at only one structure, the North Temple of the Great Ball Court. Wherever else additional height was needed for the camera, a two or a 3 m ladder proved adequate.

Minor excavations, to expose sculpture were carried on in 13 structures, namely, Structures 2B2, 2C3, 2C4, 2C10, 2D7, 2D9, 3D7, 3D8, 5B16, 5B18, 5B21, 5C7, and 6E1. After the negatives were developed and found to be satisfactory, the excavations were backfilled. Three panels of glyphs were found as a result of excavations in two structures. One panel is located across the lower part of the west jamb in Structure 5B18. Two panels were found on opposite sides of the upper most column drum of the south column at Structure 6E1.

Sherds were collected wherever they were encountered in digging, and have been turned over to R. E. Smith for further study.

KARL RUPPERT

Report on the Temple of the Wall Panels (Station 14)

YB 26:252–256, 1927

The Temple of the Wall Panels is located about half-way between the southeast corner of the lower terrace of the Caracol and the Iglesia of the Monjas group. After three days of preliminary bushing and cleaning, excavation was started on this temple on February 28 and continued for five weeks. Repair work was begun on May 2 and continued for a period of 11 weeks.

The structure consists of a solid masonry pyramid surmounted by a temple, and lying directly west of and attached to the pyramid, and forming an integral part of the whole, is a colonnade. The edifice rests on a low terrace reached by two steps, which extends 9 feet 5 inches [2.9 m] on either side of the colonnade and 20 feet [6.2 m] in front.

The pyramid measures at the base 42 feet 9 inches [13 m] north and south and rises to a height of 17 feet [5.2 m]. The east and west measurement is reduced to 37 feet [11.3 m], due to the abutting colonnade on the western side. On the northern, and southern sides of the pyramid, where the colonnade abuts it, plain faced stones, which formed the outer facing of the pyramid, were found *in situ* to a height of 8 feet [2.4 m]. This faced outer surface of the pyramid rises with a gradient of 79 to 80 degrees from the horizontal.

The core of the pyramid is formed of great sections of rough-laid masonry; large rough unworked stones, some small chips and an occasional worked stone form the fill. This was built up, section or block at a time, each block defined from the ones next it by a smooth surface formed by troweling the preceding section. The temple surmounting the pyramid measures 28 feet 8 inches [8.7 m] north and south. As its eastern or back wall had fallen, no definite east and west over-all measurement could be made; however, a section of the northern wall of the inner room, 6 feet 9 inches [2 m] long, is still standing and may well represent its original length to the exterior northeast corner, since the west chamber is only 5 feet 8 inches [1.7 m] wide. In buildings of this period, the outer and inner chambers usually have approximately the same dimensions, so it would seem that the over-all inside east and west measurements of the temple may well have been 13.75 [4.2 m] or even 14 feet [4.3 m].

Little remains of the outside facing of the temple. On the west a battered zone rises 33 inches [83.8 cm] from the floor to a 7 inch [17.8 cm] battered cornice which projects 3 inches [7.6 cm]. The middle zone rises perpendicularly above this for a few feet to where the wall is broken. In the debris at the base of the pyramid on both the northern and southern sides were found sculptured stones that may well have fallen from panels on the outer walls of the upper temple. Other sculptured stones found in the talus, which undoubtedly came from the upper temple, are portions of a mask, found on both the northern and southern sides of the pyramid, but in neither case were more than five of the 23 or 24 stones, necessary to complete the design, found. The roof of the temple was finished with an encircling row of wedge-shaped sculptures, elements of the roof crest.

The outer chamber is entered by a triple doorway 22 feet [6.7 m] wide, formed by two round column, a foot and a half [46 cm] in diameter and standing to a height of 4 feet [1.2 m]. Two other drums found on the talus in front would increase the height of these columns to 5 feet 5 inches [1.6 m]. Should the two serpent tails, which were also found in the talus in front, belong on top of these columns the height of the doorway would be increased to 6 feet 6 inches [1.98 m].

Entrance to the inner chamber was through a single doorway 44 inches [111.8 cm] wide, the present height to which the jambs now rise being 6 feet [1.8 m]. The present highest section of the temple wall is at a point 40 inches [101.6 cm] south from the northeast corner of the outer chamber, where it reaches a height of 7 feet 2 inches [2.2 m].

The floor of the temple was formed of an average 5 inch [12 cm] layer of plaster above the rough core of the pyramid. This was smoothed and painted a reddish brown, except in the triple doorway, where flagstones had been used.

In the inner room a secondary bench had been built against the back wall, resting directly on the well-smoothed and painted floor. The bench abutted the north and south walls, its base being only 20 inches [50.8 cm] from the west wall. The side of the bench is formed of two courses of stone 26 inches [66 cm] high. Above this is a 6 inch [15.2 cm] vertical cornice which overhangs 3 inches [7.6 cm]. The bench had been plastered and painted the same color as the floor. The cornice was painted a light blue. The bench was traced only 11 feet 7 inches [3.5 m] south from the north wall and 10 feet 8 inches [3.3 m] north from the south wall. At these two points it was completely broken away.

In the narrow 20 inch [50.8 cm] space between the bench and the wall at the south end were found numerous bits of pottery and two cylindrical vases. These latter were similar in shape to those found in a cache at the Temple of the Warriors, but were smaller, being only 8.5 inches [21.6 cm] in height. In the southeast corner on the floor there was an improvised altar, formed of two stones; that against the south wall being semi-circular in shape with a diameter of 8 inches [20.3 cm] and 11.5 inches [29.2 cm] in thickness. To the north of this stone was another measuring 7 by 14 by 3 inches [17.8 x 35.6 x 7.6 cm]. To the east of these stones resting on 3 inches [7.6 cm] of ash were found the two vases above mentioned.

A beautifully carved stone with its sculptured face down was found, lying midway between the jambs of the inner doorway with its western edge 4 inches [10.2 cm] west of the east line of the doorway. This stone measures 26 inches by 27 inches by 6 inches [66 x 68.6 x 15.2 cm], and is a complete panel. The design depicts two warriors facing each other, carrying staffs and atlatsls, the whole framed by a border in a naturalistic meander design. Traces of plaster and red paint similar to that on the floor still adhere to the edges of the stone. The stone completely covered and projected 4 inches [10.2 cm] west of a shallow recess cut in the floor. This recess was roughly squared and excavated to the size of the stone, which may have been placed in its opening. In the center of the recess was a cist, filled with earth, stones and traces of ash, with an opening

20 inches [50.8 cm] in diameter and having a depth of 30 inches [76.2 cm]. The sides were heavily plastered with red stucco and flared out toward the base, where its diameter increased to 28 inches [71.1 cm].

West of the inner doorway and slightly to the south were encountered four faced wall stones partly embedded in the floor, so that their smoothed surfaces were 6 inches [15.2 cm] above it. They formed what may have been a crude altar as they showed traces of fire and were badly broken.

The colonnade forming, as it were, the lower chamber to the Temple of the Wall Panels, has, like the upper temple, its long axis north and south. Inside dimensions are 52 feet 9 inches [16.1 m] by 21 feet 8 inches [6.6 m].

The outer face of the colonnade wall is formed of a battered zone 33 inches [83 cm] in height and on which rests a 7 inch [17.8 cm] battered cornice, which overhangs 3 inches [7.6 cm]; a vertical middle zone 6 feet 3 inches [1.9 m] high rises above it. The medial three member cornice has a 7 inch [17.8 cm] battered lower and upper member separated by a 5 inch [12.7 cm] vertical middle member. Resting on this cornice rose a 34.5 inch [87.6 cm] upper vertical zone, terminated by another three member cornice similar to the medial cornice, with the exception that the upper member measures 19 inches [48.3 cm] in height.

Of great interest was the finding of sculptured stone elements from panels in both the north and south exterior walls of this colonnade. The southern panel measures 45 inches [114.3 cm] high and 6 feet 5 inches [2 m] long, while the northern one is of the same height but slightly narrower 5 feet 11 inches [1.8 m]. The northern panel was formed of 15 stones and the southern of 17, of which, however, one is still missing. Monkeys, jaguars, birds, flowers, trees and men are represented in the two scenes. In the center of the southern panel is shown a tripod incense burner with a man sitting on either side. Above this is a sun disk with a group of two men on either side. Along the bottom are seven monkeys, trees, birds and jaguars filling in the background.

The northern panel has a series of 12 monkeys along the bottom. In the center of the panel is a thatched house with two men before it. On either side are trees, birds and jaguars. The upper row is formed of eight men.

The colonnade is enclosed at the north, east and south by solid walls. The antae on the western side, or front, are each 8 feet 3.5 inches [2.5 m] long, necessitating only four columns in the outer row, whereas there are six in the two inner rows. The columns average 18 inches [45.7 cm] in diameter, and those of the two inner rows are 7 feet 3 inches [2.2 m] high, not including the rectangular capitals which add 10 inches [25.4 cm]. The columns of the outer row were 6 feet 5 inches [1.95 m] high, including the capitals.

A bench 52 inches [132.1 cm] in width and 23 inches [58.4 cm] high with a 6 inch [15.2 cm] vertical cornice over jutting 2 inches [5.1 cm] is continuous along the north, east and south walls, except for the portion along the east wall between the third intercolumnar space from either end. Here the bench has been enlarged so that it is 6 feet wide at the north and 6 feet 5 inches [1.95 m] wide at the south. This enlarged portion of the bench is 10 feet in length. The height was increased 6 inches [15.2 cm], the width of its cornice. The plaster of the lower bench rounds up on to that of the cornice of the upper bench. This enlarged portion of the bench is painted red with a blue cornice, as is the lower bench.

At the time of construction of the pyramid and colonnade, access to the temple was gained by a stairway leading from inside the colonnade, similar to the one at the Temple of the Warriors but on a smaller scale. The stairway is just east of the innermost row of columns. A well, or opening, 8 feet 6 inches [2.6 m] wide in the roof of the colonnade, formed by the omission of the half of the arch directly over the stairway, left an opening for the stairway, leading from the lower to the upper level. That this was clearly planned at the time of construction of the pyramid and colonnade is indicated by the building of two lateral eastward extensions of the east wall defining the width of this stairway. These lateral extensions are 8 feet 6 inches [2.6 m] apart and extend 6 feet 7 inches [2 m] into the pyramid fill where they have irregular terminations. The walls extend from the floor level to the spring of the arch. Special arch stones finished on the face and on one adjacent side were found in the area in front of this well. These are like the stones found *in situ* at the Temple of the Warriors, which formed the ends of the exposed arches, where the stairway passed down through the opening in the roof to the floor level of the colonnade.

In a later alteration of the colonnade this original stairway had been razed; the break in the east wall through which it had passed was walled up, and the eastern side of the arch built in over the well. Behind the fill that closed the arch and leveled the floor of the temple and roof of the colonnade, traces of six steps were noted at the top of the stairway. With the removal of this stairway in ancient times there was necessitated the construction of a new means of access to the upper structure, which was accomplished by remodeling and building a new stairway in front of the colonnade. In achieving this, the two middle columns of the outer row were encased in masonry forming two rectangular columns measuring 30 inches [76.2 cm], north and south, and with a width equaling the length of the capital, that is, 24 inches [61 cm], the south and north sides respectively of the capitals being flush with the south and north faces of the masonry column.

These masonry columns were then plastered on all four sides. Later a masonry wall was built between them, extended an average of 1 foot 8.5 inches [52.1 cm] to the north of the northern one and a like distance south of the southern one. This wall was 3 feet 9 inches [1.1 m] thick and enclosed these two columns on the south, west and north. In connection with this third phase of construction a mass of masonry was built 42.5 inches [107.9 cm] to the west of these columns. This mass was faced on the east to a height of 6.5 feet [1.9 m], equaling that of the wall enclosing the columns, and with it formed the two walls of an arched passageway 42.5 inches [107.9 cm] wide and 15 feet [4.6 m] long. The mass of masonry on the west of this passageway formed the base upon which was built the new stairway. Six of its steps were found *in situ* at the base. This stairway rose in front of the colonnade and led up on to its roof, which was the same level as the floor of the upper temple.

A still later unit of construction was the placing of masonry balustrades, 36 inches [91.4 cm] wide, against the plastered north and south sides of this second stairway, and the addition of masonry blocks of the same width against the masonry wall which enclosed the round columns. These additional sections made the total length of the arched passageway 21 feet 2 inches [6.5 m].

At the base of each balustrade had been placed serpent heads. They average 37 inches [94 cm] in length 21 inches [53.3 cm] high and 24 inches [61 cm] wide and are secondary in their use here. They were originally made to be placed at the base of round serpent columns, as the concavity at the back of each indicates. This is the first example of a round serpent column, where the head is not attached to, or better forms one piece with, the lowest drum.

It is within reason to suppose that these serpent heads may have belonged to the columns of the exterior doorway at the upper temple, since they are round, and furthermore two serpent tails were found in the talus in front of this temple. The serpent heads are well formed but simple in decoration, to such an extent that they show no feather treatment. The tails are equally plain, showing only the sculptured rattles. The upward projection of the tails, invariably found in other serpent column in the city, is here lacking. In clearing the platform terrace two copper artifacts were found: one a ring 0.75 inch [1.9 cm] in diameter and the other a copper point 1 5/8 inches [3.8 cm] long.

A depression in the floor measuring 5.5 feet [1.7 m] by 4 feet [1.2 m] by 14 inches [35 cm] in depth was noted 20 inches [50.8 cm] north of the balustrade of the second stairway. This recess was outlined with faced stones and filled with earth, ash, a tripod, vase of Plumbate Ware and two stone birds with stonedisk

pedestals. The birds are 7 inches [17.8 cm] high and 9 inches [22.9 cm] long. The pedestals have a diameter of inches and are 3 inches [7.6 cm] high.

A second depression was noted extending under the bench at the east side near the point where the earlier stairway rose from the colonnade floor. This recess was 15 inches [38.1 cm] deep and filled with black ash, earth, a few potsherds, shell beads and ornaments.

Excavations in the lower terrace, on which this group stands, revealed various earlier terraces and platforms. One directly underlies the pyramid and colonnade but is not oriented with it, nor does it bear any relation to the upper structure. This platform has two lateral projections at the western end, from which on the north side a series of five steps descends 4.5 feet [1.4 m] to a lower floor level, and on the south side four descending steps lead to a similar level. A series of three steps at the extreme northeast corner below the present terrace level also gives on to a well-defined flooring. Such remnants of earlier subfloor walls, stairs and platforms show clearly how this locality, as well as every other in the city where excavations have been conducted, are underlain by remains of still earlier structures.

This group clearly belongs to the Toltec Period, 1191 to 1448 AD, as evidenced by such features as the battered basal zone, colonnade, roof crests, serpent columns and the feathered serpent and sun disk motifs in the sculptured panels. It would seem that the round form of the serpent column might be earlier than the square form, since six of the nine pairs of serpent columns found at Chichén Itzá were round, and only one pair, that in the Temple of the Wall Panels, does not have the heads of the serpents attached to the lowest drums of the columns. The early form of its serpent columns the most primitive known, the relative simplicity of the structure and its lack of sophistication tend to place it fairly early in the Toltec Period.

38.15.

EARL H. MORRIS

*Report on the Excavation and Repair of
the Temple of the Warriors (Station 4)*

YB 27:293–297, 1928

During the field season of 1928, activities at the Temple of the Warriors consisted principally of explorations within the pyramid. Until after the end of the 1927

season, it was the plan to leave unreplaced a slot in the northern face of the pyramid for the purpose of revealing a portion of the substructure of the buried temple (Temple of the Chac Mool), and to provide an entrance to the latter structure. Eventually it was decided to close this slot, and to provide access to the under, temple from the terrace at the north side of the Temple of the Warriors.

In order to make this new entrance, it was necessary to remove a cube of ancient rubble extending 17.5 feet [5.3 m] eastward from the back wall of the buried temple and from the existing slope of the pyramid southward to the vertical line of the base of the wall of the Temple of the Warriors. This mass was removed in layers of from 3 to 5 feet [0.9–1.5 m] in thickness, depending upon the solidity of the rubble at the particular moment. After each such layer had been removed, the rubble directly beneath the wall of the Temple of the Warriors was picked clean of small stones and mortar and brought to a vertical face with chinking and masonry of cement. After this procedure had been followed to a depth of 17 feet 3 inches [5.3 m], or to the floor level of the buried temple, a 1.5 foot [46 cm] wall of lime-bonded masonry was built along the south side as an additional reinforcement beneath the foundation of the Temple of the Warriors. At the same time the east side of the pit was walled, the masonry resting on a flat arch buttressed against the shell of the pyramid and the end of the south pit wall.

A reinforced concrete girder was cast at the level of the top of the second sculptured band of the pyramid to support the shell thereof, thence upward. Upon this the shell was raised with vertical inner face, and a thickness at the base of 4 feet [1.2 m], to the floor level of the buried temple. Thence upward, for 8 feet 3 inches [2.4 m], was constructed a three-sided Maya vault open on the south, for the purpose of lessening the thickness of the shell and leaving visible more of the earlier substructure beneath this arch. The north side of the arch forming its inner face, the pyramid shell, was carried up to the height of the arch cap, then continued vertically upward to the full height of the pyramid. In the fourth vertical element were set three windows like those left last year in the same panel for giving light and ventilation to the buried temple.

The pit was roofed with concrete in the same way that the under temple had been covered in 1927. A stair well was left in this roof adjacent to the wall of the Temple of the Warriors, and extending eastward beyond the eastern side of the pit. Leading down through it and on across the pit to the rear terrace of the buried substructure, was built a reinforced concrete stairway.

While the upper half of the pyramid shell, the roof and stairway, were being built, the pit was continued

downward. The rubble was removed in levels of from 3 to 5 feet [0.9–1.5 m] in thickness, depending upon its solidity or relative looseness, and the debris carted out to the north beneath the previously mentioned concrete girder. After each level was dug away, the rubble beneath the upper walls was removed and replaced with cement-laid masonry. This process was repeated until the pit reached a depth of 34 feet 3 inches [10.4 m] below the summit of the substructure supporting the Temple of the Warriors, its floor being the first terrace of the buried substructure. Then a flat arch was cast from east to west to support the base of the second battered element of the pyramid, and this feature was replaced, as well as the second sculptured band, with the exception of a window left in the latter, 5 feet 7 inches [1.7 m] wide, to admit light to the bottom of the pit. Thus there remained a tunnel through the first battered element, to permit of the removal of debris from future excavations within the pyramid.

As the pit was being dug, at the south side, in the line of ancient construction units lying eastward of the third zone of the buried substructure, were found many painted stones torn out of some vertical face and used as common fill material. The majority of these were in a remarkable state of preservation and the painting was excellent, beyond any previously seen in the excavations at Chichén Itzá. Very soon it was possible to begin fitting the blocks together, and it became evident that they were parts of a long panel 32 to 33 inches [81.3–83.8 cm] in height. For some time there was much conjecture where the panel had belonged. Its detached elements occurred in association with many stones known to pertain to the buried temple but the decoration of the walls as known from portions *in situ* left no place thereon for such a panel. Finally Mrs. Morris established the fact that these elements were parts of two panels instead of one, and that they had been the facing of the two benches which had been torn out of the inner chamber of the buried temple. So great was the desirability of completing them, that a tunnel was driven at the level at which they occurred, 24 feet [7.3 m] eastward beyond the pit. It yielded a good many of the coveted stones.

When it had been carried beyond the point where they ceased to occur, the bore was filled with masonry and a second tunnel was driven northward of, and parallel to it. This yielded others of these blocks to contribute to a total of 71, of which 38 belong to the south bench and 33 to the north one. These cover about half of the total original area of the two benches. Enough of them could be fitted together to give a complete key to the subject and arrangement of the designs upon both benches. Files of richly garbed priests and warrior figures are represented; and as will be seen from the color reproductions, which will appear in the forthcoming

volume upon the Temple of the Warriors group these murals are magnificent almost beyond belief.

After the stair pit had been completed, a tunnel was driven southward along the second zone of the buried substructure of the buried temple. It was dug a few feet at a time, then walled and roofed. The facing of the substructure provided one side, and the other was made of cement masonry to the height of the second zone. The roof consists of a Maya vault, one leg resting upon the cement wall, the other upon the second terrace of the substructure of the buried temple.

While this first tunnel was being constructed, another was begun at the western end of the south side of the same substructure. The entry was made at the level of the terrace at the top of the second multiple zone of the pyramid of the Temple of the Warriors. It was driven southward about 10 feet [3.1 m], from the north face of the stair ramp to the end of the third multiple zone which had been included within the mass of the stairway support, then turned to the east a distance of 8 feet [2.4 m] and then to the north for 2 feet [0.6 m] to lay bare a portion of the outer face of the south wall of the buried temple.

At the floor level of the east and west portions of this tunnel was found the junction of that part of the back wall of the West Colonnade which had been included within the pyramid of the Temple of the Warriors, and the buried substructure of the Temple of the Chac Mool. To follow this junction downward, a pit was sunk, branching off to the south from the east and west portion of the tunnel. The roof was brought down at an angle until it rested upon the coping of the wall of the West Colonnade. Beneath that level the first pit was extended southward as a tunnel to a total distance of 16 feet [4.9 m] from the substructure of the buried temple. The rubble of the pyramid was loose and prone to cave. In consequence the digging of this tunnel was especially dangerous. Once the upper 5 feet [1.5 m] had been completed and roofed, the excavation was continued downward, and the east wall built as the digging progressed. Eventually the level of the first terrace of the buried substructure was reached. This feature, instead of terminating with the width which it bore on the east of the substructure, continued southward as a finely surfaced platform.

From the bottom of the pit a tunnel was started toward the east, following the second zone of the substructure. The bore was continued until it met the tunnel being driven along the eastern side at the southeast corner of the base of the substructure of the buried temple. Through this tunnel it is possible to walk along 107 feet [32.6 m] of the buried substructure, which, owing to its deep interment in the pyramid of the Temple of the Warriors, is in practically perfect condition. The face consists of four zones. The basal one is a

low platform with no embellishment. The second and third have cornices, the space beneath the cornices being divided vertically into alternating jutting and recessed panels. The fourth zone is provided with a cornice like the two beneath, but is without panels. The existing southeast corner is rounded instead of angular. Thus because of the rounded corner and the paneling of the two zones, this substructure bears an extremely close resemblance to the pyramid of the Castillo.

From the southeast corner of the substructure two tunnels were driven, each for a distance of 40 feet [12.2 m], one toward the southeast corner of the pyramid of the Temple of the Warriors, the other toward the southwest. This was for the purpose of determining whether or not there were other structures included in the mass of the pyramid. The tunnel toward the southeast gave an entirely negative result. The other revealed that the first terrace of the substructure of the buried temple continued southward as a platform for a distance of 23 feet 8 inches [7.2 m]. There was no indication of a building surmounting this platform.

A careful examination of the floor known to exist from 4 to 10 inches [10.2–25.4 cm] beneath the floor of the Northwest Colonnade established the position of the north wall and anta of the colonnade to which this lower floor pertained, as well as the stubs of two rows of square columns which extended from north to south. A checking of details and levels indicated that this colonnade had borne the same relation to the buried temple (The Temple of the Chac Mool) as the Northwest Colonnade bears to the Temple of the Warriors. A doorway led through the back wall to give access to the platform previously mentioned, situated at the south base of the substructure of the buried temple.

A search for offerings was made in all of the altars that have been covered in the vicinity of the Temple of the Warriors. Of the five altars of the solid type, deposits or the proof of their previous existence were found in the three which are known to be parts of the original plans of the building in which they occur. The two barren ones are of secondary construction. Beneath the Atlantean altar in the Temple of the Warriors no deposit was found. However, deposits true to type occurred under both the northwest and northeast corners of the building itself. As a rule, the imperishable components of the offerings are significant, rather than striking or beautiful. The standard features are sandstone disks, bits of jadeite and shell. However, under the spot once occupied by the Atlantean altar of the buried temple was found an offering of unexpected excellence. The container was a jar hollowed out of a limestone block, and fitted with a stone lid. In the jar lay a turquoise mosaic disk 8.75 inches [22.2 cm] in diameter. Upon the disk, were a jadeite ball, a face and

two beads of the same material, together with shell beads from a necklace, and the skeleton of a small bird.

The wooden backing of the disk had entirely decayed, but the film of gum by which the mosaic had been encrusted upon the wood held most of the pieces of turquoise in position, so that the design was preserved. The center of the plaque is a disk of sandstone of the same kind as that found in other offerings. Thus it is evident that this particular quality of sandstone possessed some extremely sacred quality.

Work on the Temple of the Warriors was brought to a close by June 10, marking the completion of the unit of exploration and repair begun early in February 1925. The various structures composing this architectural complex have been freed of debris to the intended limit, all walls laid bare have been repaired and protected to withstand the elements, and such fallen walls as could be replaced with absolute certainty, have been rebuilt to the extent that was considered desirable.

In a study of the Temple of the Warriors complex and definitely related structures, the chronological sequence of seven distinct construction intervals has been established. Fully half of the writer's time during the 1928 field season was spent toward the completion of a monograph upon the Temple of the Warriors.

ANN AXTELL MORRIS

Report on the Mural Paintings and Painted Reliefs in the Temple of the Chac Mool

YB 27:297–300, 1928

It was planned at the beginning of the current season to complete the study of those isolated stones, bearing fresco paintings from the Temple of the Warriors, which it had not been possible last year to incorporate into large assembled areas. A number of these had already been copied but approximately 150 remained, which needed careful revision for the verification of costume and accessory details, as well as for color and techniques. In many cases an outline drawing was deemed sufficient record; in others a colored reproduction of the entire stone was considered necessary. When completed, this work included 43 color paintings and 32 outline drawings. The remainder of the stones were found to be of little importance; although

they bore traces of color, the designs were too fragmentary to permit their identification.

In addition to this work upon the mural paintings of the Temple of the Warriors, there remained the reproduction of two magnificently sculptured columns, rich with the almost perfect coloring of their original state. These had been discovered at the close of the 1927 season in the structure buried beneath the Temple of the Warriors, or, as it has been named from the beautiful Chac Mool figure found in its outer chamber, The Temple of the Chac Mool. Later excavations revealed relief after relief which equaled and even surpassed the beauty of this reclining figure, among others being the sculptured columns mentioned. These were copied in water color. In many places on these columns, the relief itself does not coincide with the sometimes carelessly made black outlines with which the painter finished his color work on the relief.

The designs on these columns, which are similar to those on the other columns from this temple, described last year, will be treated in detail by Mr. Charlott, who has made a comparative study of the relief sculpture in the entire composite structure.

Probably one of the greatest and certainly the most gratifying surprise, which the season's work brought to light, was the discovery of 71 painted stones which had been originally incorporated in the face of two benches on the north and south sides of the altar of the inner sanctuary. During the current season it was considered desirable to free the substructure of the Temple of the Chac Mool from its enclosing shell of masonry and it was the section adjacent to the eastern outer wall which produced, so unexpectedly these beautiful frescoes. When these stones began to appear sporadically, they excited great interest on account of their superb state of preservation, but for a time their provenience was a matter of conjecture. As the work progressed, however, it became evident that they had originally come from the faces of the two aforementioned benches.

These benches were L shaped, the longer axes being built against the north and south walls respectively of the inner chamber and the shorter axes against the north and south ends respectively of the east or back wall, each terminating 8 feet 1 inch [2.5 m] from the centrally placed altar. An unpainted white plastered surface remained where this bench had formerly abutted these walls in the south half of the room. The north wall and northern half of the east wall of the Temple of the Chac Mool had been torn completely away in the rebuilding operations coincident with the construction of the Temple of the Warriors, and the dimensions given for the north bench are based upon the assumption of a symmetrical ground-plan with reference to the east and west axis of the temple.

Calculations made from this unpainted silhouette, as it lay against the south wall and the southern half of the east wall, established the fact that the total length of the painted face of each bench had been 25 feet 4 inches [7.7 m] and its original height 3 feet 4 inches [1 m], the slightly jutting cornice being 7 inches [17.8 cm] in height. The total height of the assembled stones was within half an inch of the unpainted section on the south and east walls. The design on these benches was found to have been framed with broad blue bands, and splashings of blue paint were found at the point where the bench had formerly joined the black painted wall. The stones, from the lower edge of the benches were themselves splashed with red paint from the numerous repaintings of the red floor.

More conclusive proof of the former positions of these stones was derived from a study of the stylistic evidence. Two major groups were immediately noted: 1. Pieces executed in a polychrome technique with considerable nicety of detail; and 2. Pieces, broadly, and crudely treated, done almost exclusively in shades of red. These were found to be parts of the two separate benches, the former belonging to the bench on the right, or south side of the altar, the latter to the bench lying to the left, or north of the altar. The altar was the logical focus of interest in the sanctuary, and the human figures on these benches were found to be orientated so as to continuously face it.

The stones belonging to the south bench, 38 in number, fall into three groups. The human figures of one group when assembled were found to face to the left, and this section coincides with the 14 feet 6 inches [4.4 m] required for the face of the bench lying along the south wall. A second group with their figures facing in the opposite direction when fitted together, exactly fill the 4 feet 8 inches [1.5 m] of the face of the bench nearest the altar. It seems probable that this reverse facing of the figures of the second group was due to the desire to have them look toward the sanctuary and the front of the altar. A corner stone with incomplete figures facing each other confirmed this hypothesis. The third group, occupying the middle section of the bench, that is, that lying along the east or back wall of the sanctuary, had been executed by a different hand than the stones lying parallel to the adjacent section of the bench along the south wall, even though its figures faced in the same direction. This stylistic difference made possible a separation of the stones of these two groups, one from the other. Only slightly more than half of the stones were found, although careful search was made for the rest. Their re-use as fill material, mixed with plaster and rubble, had fortunately resulted in but slight damage to the surfaces.

The subject of the painting is a file of human figures seated upon benches covered with jaguar skins.

There are warriors panoplied with shields and spears, and priests offering bowls of incense in their extended hands. Sufficient of the design remains to establish the general details of dress and ornament for all the types of human figures represented.

The north bench, as previously stated, was more crudely painted and; in addition, its component stones had suffered rougher treatment in their re-use. Nevertheless, it was possible to identify enough to permit the reconstruction of the design of the entire panel. The human figures, in this case only warriors, are seated upon jaguar stools. The bench along the north wall shows these jaguar stools or seats standing full face to the spectator, head, forelegs and shoulders visible; the tails are drawn in, so that they may be seen between the animal's forelegs. The seated human figures are drawn in profile as are also the jaguars in the remaining two sections of the bench, that is, that lying against the east or back wall and that facing the altar.

Throughout the remainder of the Temple of the Chac Mool, the preliminary outlines are sketched with a flowing red line, but on this bench the outlines of the jaguars were only roughly indicated by scratching them in the wet plaster. These outlines perforce are angular and ugly and very fortunately were not followed in the slightest degree by the artist in his final work. In the upper part of the bench no preliminary outlines were used at all, the color being applied directly to the plaster in blocked-in masses, which were subsequently outlined with a heavy black line. This unusual technique has been found nowhere else in the city up to the present time.

Both benches show various departures from the usual fresco treatment, the most striking of which are a lavish use of masses of dark paint laid on a red ground, resulting in a rather unique lack of contrast, and the practice of covering the entire surface, preliminary to painting, with a glutinous yellow-white mixture before the subsequent colors were applied. This gives a marked opacity to these particular frescoes, in strong contrast to the clear water-color appearance of the frescoes in the Temple of the Warriors.

A study of dress and ornament has proved of great interest, but lack of space limits even a brief description of these details. The monograph on the Temple of the Warriors, now in course of preparation, will include a comparative study of the subject-matter of the frescoes, as well as detailed analyses of the colors employed, and other problems of technique which have arisen in the course of the work.

38.17.

JEAN CHARLOT

Report on the Sculptures of the Temple of the Warriors and the Temple of the Chac Mool

YB 27:300–302, 1928

As the investigation of no new architectural unit was carried out in 1928, the time of Mr. Charlot and of his assistant, Mr. Houser, was devoted to a completion of work already under way at the Temple of the Warriors and adjoining structures.

Drawings of the sculptures on the columns of the Temple of the Chac Mool, as well as a few left in the Temple of the Warriors, the dais of the North Colonnade and the dais of the Northwest Colonnade were completed this season. The designs on the columns in the Temple of the Chac Mool were described in [Chapter 38.12], but only a few had been drawn at that time.

This season the designs on these columns were copied in line drawings with color notes added in five flat tones, with a view to securing standardization of color reproduction in the lithographic plates. Thirteen drawings with the corresponding color notes were made which, with the 17 copied in water color by Mrs. Morris, make a complete record of the bas-reliefs that have survived in this temple.

The columns in the Temple of the Warriors had been copied, in 1926 in line drawing, independent color notes on transparent paper having been made at the same time. These color notes were transferred this season from the transparent sheets to the drawings themselves, after having been reduced to the five standardized tones adopted for lithographic reproduction.

Another important piece of work concluded during the present season was the painting of the front of the dais in the North Colonnade. The two shorter sides of this dais had been copied in oil in 1927. The front, measuring more than 16 feet in length, was copied this season, also in oil, natural size. The two shorter sides of the dais in the Northwest Colonnade had been copied in 1926. Owing to the extensive copying in the field, which has been going on since then, and the technical improvement resulting therefrom, it appeared advisable to retouch the copies of these two sides, painting directly from the corresponding originals.

In addition to the foregoing, Mr. Charlot made drawings as well as water colors of a number of disassociated sculptured units, the original provenience of which is unknown.

Two-color copies were made of the remnants of the beautiful panel composed of flowers and animals found in the fill of the pyramid of the Temple of the

Warriors. The sculpture is in rather high relief and presents unknown flowers on graceful sinuous stems ornamented with bud-like leaves. Different insects and birds feed upon them. Although much stylized, the butterflies are still recognizable as such, their wings transformed into two flowing panaches of quetzal-like feathers, the head, with its extended proboscis, retaining many of the original entomological characteristics. Among the birds which could be identified are the crested parrot and the hummingbird, the latter in its characteristic position of sucking the flower while on the wing.

The relief, vividly colored, is in strong contrast to the plain, white background. A few stones were found, which are doubtless parts of the same panel although they show no coloring, being done in black and white only. As this duochrome treatment was a preparatory process before color was applied, it is probably to be assumed that this panel, like many sections of the friezes on the pyramid of the Temple of the Warriors, had been completed all but its polychromy, and was then discarded because of some subsequent architectural modification.

The fragments of the serpent columns belonging to the Temple of the Chac Mool, uncovered in 1926, consist of parts of the two tails and the two heads. The better preserved tail was copied in colors, while a line-drawing was made of the other. Both present, in addition to the usual tail-rattles and feathers, panels consisting of three Atlantean figures each, the figures bearing representations of shells and turtles.

The more important of the two heads, that still having a section of its corresponding columnar shaft, was also copied in color. Its style is strikingly different from that of the similar heads in the Temple of the Warriors. Although the subject matter is the same in each case, the plumed serpent, the treatment, which in the earlier temple is more of an esthetic abstraction, tends in the later Temple of the Warriors to become fairly realistic. The different parts of the serpent's head are represented, but without interfering with, or modifying the primitive squareness, of the original block of stone. Here is an interesting stylistic link with some of the sculpture at San Juan Teotihuacán, especially the figure of an ocelot made of alabaster, and a heroic sized goddess in the National Museum at Mexico City.

On the serpent column from the Temple of the Chac Mool, the feathers are painted red; the fangs, of semi-spherical shape, are pink. The outline of the mouth, as well as the scrolls issuing from it, is yellow. The belly of the snake is yellow and the rattles are blue. A narrow horizontal band of blue and yellow encircles the body at about one-third of its height.

Three line-drawings were made of sections of the three friezes running around the pyramid of the Temple

of the Warriors, the examples chosen, illustrating the different elements (men holding ceremonial bars, animals and birds) found on each band. This last work brought out a new fact, showing the ingenuity with which the builders used their wide knowledge of perspective. While on the lowest frieze, which is at the level of a man's eyes standing at the base of the pyramid, the feet of the reclining figures rest directly on the cornice just below them, in the middle and top friezes there is a space left between the feet and the cornices below them. This was done so that, in the diagonal perspective resulting from looking up at these friezes, the feet of the figures would not be hidden by the cornices projecting below them, but appear to rest directly on them. So many and so diverse are the successive layers of paint on these elements, that exact color reproduction would only be misleading. It seems that in the case of the last coat at least, the human figure and its accessories were painted blue, except for the belt, which is green; the eagle is black; the jaguar, yellow; and the unidentified animal which has been called the "woolly" is treated with a hachure of black and white to represent fur. The background everywhere is red.

A copy was also made of the charcoal sketch of an Atlantean figure, found on the unpainted base of the south wall of the sanctuary of the Temple of the Chac Mool, where the bench had formerly stood. This figure is of especial interest, in that it may be the only example of a working drawing for a piece of stone sculpture before execution, which has come down to us. All the field notes necessary for the preparation of a report on the bas-reliefs of the Temple of the Warriors were made, and two-thirds of the text itself was completed before Mr. Charlott left Chichén Itzá. Also, about 200 line drawings were made, to be used in illustrating the text, in addition to the copy for the full-page illustrations and color plates.

PAUL S. MARTIN

*Report on the Temple of the Two Lintels
(Station 7)*

YB 27:302–305, 1928

The repair of the Temple of the Two Lintels was completed on April 28. During the 1927 field season the

four exterior walls and the two interior partitions had been re-erected to the level of the lowest member of the medial cornice, that is to say, to a bout half their original height. During the current season, these were completed and the building roofed over.

When work was started on this building in the spring of 1927, it was evident that all the façade above the medial cornice had fallen, with the fortunate exception of a single section of the back wall, which stood to within two courses of the original height. This section served as a pattern for the reconstruction of the entire upper zone, since here, *in situ*, was a complete cross-section (lacking the two courses above mentioned) of the original façade-cornices, inter-cornice element and the decorated panels of the upper zone. There are two types of these decorated panels which alternate with each other clear around the building, the first consists of X-shaped stones, separately cut and fitted together like a mosaic, giving the appearance of lattice-work; the second is composed of four round columns, occupying the same space, both vertically as well as horizontally, as the lattice panels. Since no cut stones were found either in the front or rear, which differed from the elements of the two types of panels, already *in situ*, it seemed safe to assume that the fallen elements should be replaced in the same manner.

The story of the east and west façades is slightly different. The following sculptured elements came to light during the excavation of the two ends of this temple. 1. Five round columns, of the same size as those in the front and rear façades, but banded in the middle with a conventionalized knot, found at the back corners. 2. The several lateral elements of a corner mask found at the front corners. 3. 28 X-shaped stones.

Apparently the upper zones of the ends of the temple were composed of 1. These five special columns, contiguously placed; 2. A solid panel of 28 X-shaped stones, arranged in four horizontal rows of seven X-shaped elements each; and 3. The lateral elements of corner mask panels. From the rear of the temple, only one of these "knotted" columns was visible at each corner.

Justification for this reconstruction of the design is found, first, in the fact that all the sculptured elements exactly fill the space available for them; and, second, the old plaster marks still adhering to the cornice elements corroborate the above arrangement. For a long time, indeed, the positions of these columnar elements were uncertain, but the discovery of the corner stone of the cornice upon which they had formerly rested furnished irrefutable proof of their original arrangement, the ancient plaster marks coinciding to the millimeter with the number of columns actually found.¹

Complete repair of this temple has been possible only because practically all the original material was at hand. For example, only 11 X-shaped stones were missing out of an original total of 264.²

In rebuilding the arches, or corbelled vaults, no temporary forms to sustain them were necessary as in the construction of true arches.

Each vault stone was specially cut so that, when placed in position in the wall, its center of gravity lay well toward its butt so that it could not fall forward; and, to make each stone even more secure, a large rock was placed over the butt, holding it in place until the entire roof was built. A few of the beveled vault stones had to be replaced because some of the originals were too badly weathered and broken to be used again.

The temple proper rests on a platform decorated with sculptured designs; the front has a continuous lattice pattern composed of small separate X-shaped stones, terminating at each end with a mask panel. The platform at the rear consists of alternating panels of small round columns and a square scroll motive.³ For some unknown reason this beautiful platform had been covered at some later time in order to raise the whole terrace level upon which the temple stood. In so doing, the long curved noses of the corner masks were broken off and much of the delicate relief, including the animals behind the ear plugs, was covered with a stucco finish.

The lower zone, that is, the portion of the façade immediately above this beautiful base, is a vertical wall, 6 feet high; it is plain, except for three doorways on the north side.

Above the lower zone and set between the two outer members of the medial cornice, is a continuous course of dentated elements, set at an angle of 60°, the spaces between them being filled with triangular-shaped stones.

Resting on the topmost member of the medial cornice are the alternating panels of lattice and columns already mentioned. At the two front corners of the upper zone are mask panels of truly magnificent workmanship. They rank among the finest in the city. The upper zone is in turn surmounted by the conventional three-member cornice. The lowest member is battered, and is 9 inches [22.9 cm] high; the second is a vertical course 6 inches [15.2 cm] high, and the terminal member is a battered coping 18 inches [45.7 cm] high.

Formerly the platform and upper zone were painted red; the lower zone was undoubtedly plastered, but was not painted. The whole effect is one of dignified simplicity and striking beauty. This building is a gem of pure Maya architecture and shows no Toltec influence.

Although this temple has three doorways, at the close of the 1927 field season only two lintels had been

found, namely those corresponding to the two end doorways. It seemed almost certain, however, that the middle doorway must originally have had a stone lintel as well, and that it had either been removed in ancient times and re-used elsewhere (a very common practice), or that it had been made of wood, and had decayed. Therefore, last year, in order to replace the cornice above it, it was necessary to find a substitute for this missing lintel. A plain stone lintel of the proper size was removed from an old water trough at the hacienda, and was used over the middle doorway in place of the missing one.

This year a more thorough bushing of the area near the temple resulted in the recovery of three pieces of the missing lintel, which were found not more than 75 feet [22.9 m] from the front of the temple. These pieces had been refashioned into metates, or grinding stones, and composed about two-thirds of the original lintel. These grinding stones, the faces of which are carved with hieroglyphs, fit together, making it quite evident that they were parts of one and the same stone. Moreover, the measurements of the glyphs correspond exactly with those of the glyphs on the lintels over the other two doorways; finally the proximity of these pieces to their former position lends additional color to the conclusion that at one time they were parts of the lintel over the middle doorway. The discovery of the fragments of this lintel was gratifying, because it removes any doubt as to its former existence.

In addition to the discovery of the missing lintel, the more thorough bushing of the present season revealed the fact that all around the temple on the terrace itself were many small square structures, of which only the very crude foundation walls remain. Each structure measures about 10 feet square [0.09 sq m], and the foundations are composed of cut and uncut stones, both round and square. The walls of one structure abut those of the adjoining ones, forming a continuous series of small cell-like rooms. The ground-plan is not unlike the ground-plan of some of the structures in the Pueblo region of the southwestern United States.

Almost every one of these structures contains a grinding stone, or metate, either whole or broken. It was in two of these small cell-like rooms that the pieces of the hieroglyphic lintel were found. It is probable that the roofs of these buildings were of jacal, that is, palm thatch, and the sides of brush and mud.

The use of these structures is purely conjectural. They may have served as places for grinding corn; or again they may have been dwellings, although they are very small, and show no other evidence of domiciliary use, such as hearths, etc. There are from 50 to 75 of them.

At the edge of the southeast corner of the terrace is chultun, or cistern, for collecting and storing rain water.

This chultun and a nearby well were undoubtedly the sources of water for this temple and the people living in its immediate vicinity.

NOTES

1. Throughout the reconstruction of this temple the ancient plaster marks repeatedly served as guides to the former position of doubtful carved elements. They were invisible in reconstructing the corner masks, and may well be called archaeological "divining sticks."

2. The interest of the Maya Indian laborers in the reconstruction of this temple was shown by the fact that they volunteered to bring enough similar X-shaped stones, from the village of Pisté, three miles [4.8 km] distant, to make up this shortage.

3. This motive is identical with that found on the platform of the East Annex of the Monjas.

38.19.

KARL RUPPERT

*Report on the Outlying Sections of
Chichén Itzá*

YB 27:305–307, 1928

It has been felt for some time, that, in order properly to estimate the size of Chichén Itzá and to reach an appreciation of the position it held in the Maya world of the thirteenth, fourteenth and fifteenth centuries, it would be necessary to supplement the more intensive excavation work of the past four seasons with more extensive exploration of the outlying sections of the city. For this purpose a partial reconnaissance of this area was made this year. The regions explored include the territory east, southeast, south and southwest of the hacienda, for a distance of 3 to 4 km. Where it seemed advisable to trace ground-plans, minor excavations were undertaken.

During the course of the reconnaissance some 27 stations were examined, which may be classified roughly as follows: 1. Low mounds; 2. Isolated terraces, with or without superstructures; 3. Groups of terraces and structures; and, 4. Stone quarries.

Examples of the first group vary greatly in extent. Walls may always be traced, often defining well-planned and extensive structures. The walls, however, are very low and the small amount of debris together with the absence of beveled arch stones, leads to the assumption that structures of this group were of relatively small importance.

The second group includes most of the stations examined. In some cases no trace of a structure was noted on these terraces; others had a single square or rectangular mound in the center. One such mound or raised area had, at its base, a sacrificial altar like the one found by E. H. Morris at the Temple of the Warriors in 1926 [Chapter 38.10].

In some cases, covering extensive sections of these terraces, there are irregular, square and rectangular areas outlined, by a single course of stone. These may have been living quarters or work rooms, as many metates are found in connection with remains of this type.

Other terraces have one or more rather high mounds surmounted by a temple, or again these several types of structures may all be found on a single terrace. Sometimes isolated structures not on terraces are associated with these terrace groups.

One station, known locally as the "Group of the Chultun," is an excellent example of this kind. This name has been given to it, because of a single chultun here, which has a masonry drain 3 inches [7.6 cm] deep by 5 inches [12.7 cm] wide, extending from its orifice to a group of buildings on the same terrace behind it.

Besides terraces, platforms and colonnades, this group also has a type of building which is not unlike the Market Place at the Group of the Thousand Columns. This structure faces west and is composed of a colonnade, having its long axis north and south. A single opening in the east wall gives into a court some 60 feet square. A covered corridor had passed around all four sides of this court. The roof, which was flat, was supported by 20 round columns. In the middle of the east wall is a doorway leading into a small recessed chamber. During the reconnaissance, four such quadrangular structures were noted.

West of this quadrangular structure is what appears to be an unfinished ballcourt. The two walls are 50 feet apart and 80 feet long. The west wall is some 6 feet higher than the east wall. Because of this fact, and the absence of out stone, it seems that this ballcourt may have been under construction.

Southeast of the hacienda, a distance of half a kilometer, a second quadrangle was discovered. This is 50 feet square, and had its entrance on the north side and an opening on the east side leading into a small chamber. The north exterior doorway is 8 feet wide. Against each jamb there is a pilaster, 29 inches [73.7 cm] wide. The faces of both of these pilasters are sculptured with hieroglyphs arranged in three vertical rows of nine each, making a total of 54 glyphs for the two pilasters, each glyph block being 8.5 inches [21.6 cm] square.

When these pilasters were found, they were not complete. Search through the nearby bush, however, brought to light five of the missing pieces. The two blocks, which formed the ultimate course of each pi-

laster, were located 150 feet [45.7 m] to the north, having been re-used in the construction of the southeast corner of a small platform. The opening between these hieroglyphic pilasters had been blocked at some later time, and thus the entrance to this court closed.

A kilometer east of the hacienda, there is a group belonging to the third type, of more than usual importance, since it contains a circular building. This building rises from a platform some 20 feet [6.1 m] in height, which is located at the eastern edge of a large terrace. In the center of this terrace is a low mound, and at its western edge is an ancient roadway leading off in a westerly direction.

The circular building itself is indicated only by the enclosing walls which stand to the height of the lower cornice, just above the battered zone. It contains but a single chamber, and is 23 feet [7 m] in diameter inside. As no beveled arch stones were noted in the debris, it seems likely that the walls above the battered zone, as well as the roof, had been of wood and rubble.

Two clearly defined stone quarries (Group 4) were examined, one to the southwest of the hacienda and the second three kilometers west by north of the village of Pisté.

At the latter station, two large roughly worked blocks had been taken out and left some 20 feet [6.1 m] from the rock ledge from which they had been quarried. Both of these blocks were broken, which may account for the fact that they had been abandoned. Each block measures 9 feet 4 inches [2.8 m] in length, 4 feet 3 inches [1.3 m] in height, and 3 feet 10 inches [1.2 m] in width. No artifacts were noted in or around either of these quarries.

Even the incomplete results of the partial reconnaissance made during the current season indicate a much greater building activity than had at first been suspected, and fortifies the conclusion, already reached, that Chichén Itzá was the largest center of the New Maya Empire.

38.20.

KARL RUPPERT

Report on the Excavation and Repair of the Caracol (Station 5)

YB 28:303–310, 1929

Excavations at the Caracol group during the current season may be considered under three heads: I. The Caracol; II. The West Annex; III. The South Annex.

I. THE CARACOL

Excavation of the north, east, and south faces of the upper terrace was commenced on January 23, in order to permit the repair of these walls and to examine the sculptured and faced stones which had fallen not only from the upper terrace, but also from the Caracol proper above the 5-member cornice.

The following sculptures were recovered from the east side, two contiguous cornice elements presenting glyphs, which had been parts of a serpent with hieroglyphs carved on the body; other parts of this same serpent-cornice without glyphic treatment; elements from the mask-panel above the east doorway; a seated human figure in full round; and various decorative elements which may have formed parts of the panel of which the seated figure was the central element. The sculptured material, found on the north side was about the same as that on the east side.

Fifty-seven stone incense burners have been recovered from the Caracol. Some of these may have been used in connection with the tower itself as two were found relatively high in the debris on the upper terrace; but it is believed that the greater number were placed on the parapet of the upper terrace, as indicated by finding 10 of them spaced at regular intervals in the debris across the base of the terrace wall on the south side.

To ascertain the nature of the foundation supporting the great weight of the central core of the tower, a pit was dug in the inner corridor directly inside the south doorway. The foundation was found to be composed of large rough stones, well embedded in mortar to a depth of 13 feet 8 inches [4.2 m]; below this level the fill contained comparatively small amounts of mortar.

At a depth of 5 feet 2 inches [1.6 m] below the floor of the corridor several horizontal tunnels were noted, averaging 4 inches [10.2 cm] in width and 8 inches [20.3 cm] in height. They are very definitely indicated, although made of rough stone.

Thirteen feet 1 inch [4 m] below the floor and directly beneath the center of the core of the Caracol proper was a stone-lined and roughly circular cist, 12.5 inches [31.8 cm] in diameter and 19 inches [48.3 cm] in height. The cist was covered with stones and the floor was of untroweled lime mortar.

In the center of the floor of the cist a vertical shaft, 2.5 inches [6.4 cm] in diameter, extends to a depth of 27.5 inches [69.9 cm]. The upper 7 inches [17.8 cm] of this is roughly lined with mortar showing vertical striations which would tend to indicate that the shaft had been formed by laying wet mortar around a pole, and withdrawing it after the mortar had partially set. Four horizontal tunnels leading away from the sides of the

cist have the following bearings: N 24 degrees 30 minutes E, N 65 degrees 30 minutes W, S 37 degrees 5.18 minutes E, S 65 degrees 30 minutes W. They average 5 inches [12.7 cm] in width and 8 inches [20.3 cm] in height.

An olla had been placed in the hollow directly over the small opening in the floor. It is 9 inches [22.9 cm] in height, of dull red-brown ware with heavy brushed decoration. It was half filled with earth in which were mixed pieces of a sandstone disk similar to those found by E. H. Morris at the Temple of the Warriors [Chapter 38.15 this volume] and elsewhere. This disk had a diameter of 5 inches [12.7 cm]. There were also found seven pieces of hematite mosaic, a small stone button, one surface of which was painted red, and a squared shell ornament.

In the process of clearing the debris on the east side of the upper terrace, a circular substructure, the original upper terrace, was discovered. This rested directly on the lower terrace, and rose to a height of 11 feet [3.4 m], terminating with a 15 inch [38 cm] vertical cornice. The diameter of the newly discovered circular platform is approximately 53 feet [16.2 m], that is, 17 feet [5.2 m] greater than the Caracol tower.

Surrounding the circular platform, except for a section of about 40 feet [12.2 m] on the western periphery, is a bench 4 feet 3 inches [1.3 m] wide and three feet high finished with an 8 inch [20.3 cm] vertical cornice. As yet no stairway has been found leading to the summit of this circular platform. The openings or mouths of small horizontal tunnels were noted at various levels in the facing and at the base of the bench. In some cases these tunnels were blocked by the later fill material which had been built around the circular platform, and in other cases they had been prolonged by crudely built passages in the fill. These tunnels are not always straight, as for example, one on the west side makes two turns before it opens through the faced wall of the upper platform. Since the upper platform has not yet been completely excavated, the relationship between these openings and the tunnels encountered in the shaft sunk in the inner corridor of the building is as yet unknown.

A cache of skeletal material was encountered in front of the west doorway at the edge of the cornice of the original circular substructure. The material extended from 7 to 25 inches [63.5 cm] below the surface but not more than two feet west of the cornice. The first indication of this cache was the discovery of a nest of cranial fragments belonging to at least 13 different individuals; altogether, scattered throughout the fill, were found, complete or in part, sections of 18 different lower jaws. Even though this material was in very poor condition the area occupied by each skull was clearly indicated in the fill. They were placed in very closely

packed rows, three being found under the cornice. No attempt at orientation had been made and long bones were scattered indiscriminately throughout the area.

From the position of the material and the fact that stones were wedged in between bones as if purposely, there can be little question that these are secondary burials. Funeral furniture includes sherds of a rather plain incense burner and the lower jaw and two vertebrae of a deer.

As excavations were continued around the cornice toward the northwest, an olla, 14 inches [35.6 cm] in diameter and 15 inches [38.1 cm] in height, was uncovered 4 inches [10.2 cm] below the surface. It was half filled with ash under which were two excellent obsidian flakes, 4 and 4.5 inches [11.4 cm] in length, respectively.

A trench in the floor of the niche between the double stairway leading to the summit of the second terrace exposed a masonry platform measuring 84.5 inches [2.1 m] in length, 70.5 inches [1.8 m] in width, and 12 inches [30.5 cm] in height. Resting on this platform were two round columns. The top of the platform is 4 inches [10.2 cm] below the base of the sides of the steps and extends under them a distance of 17.5 inches [45 cm] on the south side and 11 inches [28 cm] on the north side. The back wall of the niche rests on top of this platform. The northern half of the platform, as well as the column resting on it, was painted black, while the southern half and the southern column were painted red.

Scattered throughout the dirt fill of the area between the stairways, to a depth of 16 inches [41 cm], were found fragments of human bone. There were two foci of concentration of this material—one along the southern side of the niche, 33 inches [84 cm] west of the platform, and the other 45 inches [1.2 m] west and on the east and west axis of the niche. The latter represents secondary or disturbed burials as sections of skulls and teeth were found scattered throughout the fill. Skeletal material recovered includes the following teeth and miscellaneous bones: 43 molars and premolars, 33 incisors, 24 canines, one lower jaw, one right and one left tibia, one humerus, one clavicle, two ulnas, one atlas, besides fragments of ribs, long bones and skulls. Burial objects include 90 jadeite beads, two pieces of obsidian and a few miscellaneous sherds and portions of shell.

During the season of 1927 two drains were found in the floor of the lower terrace [Chapter 38.13]. This season a third was found on the east side, 107.5 feet [32.8 m] north of the southeast corner of the terrace. Only a section of its south and west faces remains *in situ* due to the fall of the cornice above at this point.

Excavations along the parapet of the lower terrace, south of the main stairway, established that it

had been 44 inches [1.1 m] in width and at least 33 inches [0.8 m] in height. Four openings, somewhat regularly spaced, which pierce this section of the parapet at the level of the floor of the terrace, may have served as drains. They vary in height from 6 to 10 inches [15–25 cm] and in width from 8 to 12 inches [20–31 cm]. A small stairway built against this parapet will be described in connection with the West Annex.

The stairway leading to the top of the lower terrace was subjected to a number of alterations. In its final stage it consists of two sections. The four lower steps have 3 foot 3 inch [91 cm] treads and 10.5 inch [27 cm] risers. The three lower steps have a gradient of 78 degrees with the horizontal, and the fourth one of 65 degrees. This flight of four steps is 71 feet [21.6 m] long and gives on to a platform 21 feet [6.4 m] wide, which projects 8.5 feet [2.6 m] beyond the upper section of the stairway at both ends. However, with the subsequent construction of the West Annex, the southern foot and a half [46 cm] were covered by the platform of the Annex. The western face of this platform rises with a batter equal to that of the riser of the final step, while the north and south-faces are vertical.

The second section of the stairway begins to rise at a point 13.75 inches [34.9 cm] behind the front line of the platform. This portion of the stairway is 43 feet 10 inches [13.4 m] wide and its medial axis coincides approximately with the medial axis of the lower flight of steps. The risers average 9.8 inches [24 cm] high, and the treads, 13.75 inches [35 cm] wide. At either side were balustrades, 18 inches [46 cm] in width, each carved with a pair of intertwining serpents. The two heads and two tails belonging to the tops of the balustrades were recovered. The two tail stones were of highly specialized shape being carved so as to sit vertically, directly below the protruding heads, the tip of each tail extending beyond the outside edge of the balustrade.

An earlier period in the construction of the upper section of the stairway is shown by the painted lime-plaster floor of the platform, which extends under the balustrades to the facing walls of the stairway and also under the steps on the west side for a distance of 7 feet 9 inches [2.4 m]. This indicates that at one time the stairway was without balustrades and rose at a greater angle.

The lower section of the stairway, as well as the platform, rested on a well polished lime-plaster floor, painted red. A pit sunk into the platform at the south, and a tunnel driven in for a distance of 12 feet [3.7 m] under the stairway at the north, showed this same red floor continuing under the platform and stairway and curving up against the west face of the lower terrace and against the roughly plastered section of masonry protruding from the terrace, and extending under the

stairway. The significance of this section of masonry and the floor curving up against it can not be determined until after further excavation.

Abutting the first riser of the lower section of the stairway at a point 14.5 feet [4.4 m] south of its northern edge is a still lower step, which gives directly on to a paved stone roadway, 13 feet [3.96 m] wide. This extends in a northwesterly direction some 120 feet [36.6 m] to the south wing of a building called no. 6 on the Maudslay map of Chichén Itzá and described by him as "a tumbled heap of stones now about 4 feet [1.2 m] high, which may at one time have supported a roofed building."

Finally the south balustrade of this stairway, composed of a pair of intertwining serpents, has been restored to its original position so far as possible, although a few of the sculptured blocks are still missing.

When Mr. Reygadas, Director of Archaeology for the Ministry of Public Education, visited the Caracol on March 9, he expressed the wish that the 5-member cornice of the Caracol, as well as the arch of the outer corridor, might be entirely replaced except for the section on the east, where it had fallen en bloc without disintegrating, to within a few feet of the upper terrace floor. With this in view, work was started on the repair of the outer east wall, and continued until the 5-member cornice was entirely replaced except for this single section.

The exterior wall of the Caracol has been raised to a height of 46 inches [1.2 m] above the 5-member cornice, which involved replacement of the masks over the north and east doorways. The arch of the outer corridor has been repaired to an equal height on the inside. The fallen walls of the second terrace have been replaced and the parapet raised to the highest surely established level.

II. THE WEST ANNEX

The West Annex consists of a low platform built against the west side of the lower terrace of the Caracol, to the south of the stairway, surmounted by a small temple. The platform measures 51.8 feet [15.8 m] on the north, 46.5 feet [14.2 m] on the south, and 64.5 feet [19.7 m] on the west. The battered facing rises with a gradient of from 76 degrees to 80 degrees, to a height of 7.7 feet [2.4 m] where it terminates with an angular cornice, overhanging 3 inches [7.6 cm].

Two stairways give access to this platform. The principal one, on the west side, 24.7 feet [7.5 m] from the northwest corner has a width, including the balustrades, of 15.3 feet [4.7 m]. Each balustrade was 18 inches [46 cm] wide and carved in low relief to represent a serpent. The serpent heads, which had stood at the tops of the balustrades, were not found.

The other stairway is on the north side of the platform and measures 7 feet 10 inches [2.4 m] in width, including the two 15 inch [38 cm] balustrades. The outer facing of the western balustrade rises vertically from a point at the top of the battered face of the platform reached by the lower section of the Caracol stairway.

In the debris to the west of the platform and south of the main stairway were found six large, finely dressed stones, the original positions of which have not yet been determined. These stones are 28 inches [71 cm] in height, battered on one face and vertical on the other. These two faces, as well as the top, have been worked and plastered. A seventh stone similar to these was found on top of the platform, 4 feet [1.2 m] south and 2 feet [61 cm] west of the north *anta* of the temple proper. The finding of this one stone above the platform suggests that they pertain to the temple rather than to the platform. Placed side by side vertically as was undoubtedly their original position, they have a combined length of 7 feet 11 inches [2.4 m].

The temple measures 28 feet [8.5 m] east and west by 46.5 feet [14.2 m] north and south. It is so placed on the platform that a narrow passageway only 22 inches [56 cm] wide has been left between its back wall and the battered western face of the lower terrace of the Caracol.

A cross-section of the west wall of this temple reveals a vertical zone rising from the platform to a height of 7.5 feet [2.3 m]. Upon this rests a three member cornice, having battered lower and upper members, 9 inches [23 cm] high each, separated by a 6 inch [15 cm] vertical member. No portion of the wall above the first member of this cornice was found *in situ*; however, the height of the fallen upper part of the façade may be calculated with reasonable accuracy from data recovered in the course of excavation. It seems likely that above the three-member cornice here was a vertical 3 feet 6 inches [1.1 m] high, upon which rested another three member cornice similar to the first, with the exception that the top member is 18 inches [45 cm] in height. This gives a total height for this temple of 15.75 feet [4.8 m].

The upper vertical zone, with the exception of the east side which was plain, was decorated by a continuous band of simple U-shaped motifs 8 inches [20 cm] in height, incised on the wall-stones, and large decorative niches in the middle of each side. In each niche a seated human figure forms the principal motif. The figures in the north and south niches are seated cross-legged. Although these are not as finely executed as those found by E. H. Morris in 1926 in front of the Northwest Colonnade, they are in the same style. The figure from the north niche has a bird beak and a tubular nose plug.

The temple has two chambers; the outer one is a colonnaded hall having two rows of four columns each, which support the corbelled arch roof. It is 41 feet 6 inches [12.6 m] long by 14 feet wide [4.3 m], the long axis running north and south. The *anta* have an average length of 3 feet 5 inches [1 m]. The round columns average 19 inches [48 cm] in diameter and with their rectangular capitals, have a total height of 6.5 feet [2 m]. Three stones bearing the incised U-shaped motif were found *in situ* in the facing of the east wall.

Entrance to the inner chamber was gained through a doorway 4 feet [1.2 m] wide, the jambs of which were standing to their original height of 6.5 feet [2 m]. The inner chamber is 40 feet 9 inches [12.4 m] long by 7 feet [2.1 m] wide.

Directly in front of the doorway there is an altar 13 feet [4 m] long, 4 feet 10 inches [1.5 m] wide, and 2 feet 2.5 inches [67 cm] high including the 6 inch [15.2 cm] vertical cornice, which overhangs 3 inches [7.6 cm]. Faint traces of geometric designs in red, green, tan and black were noted on the cornice, while on the sides large yellow flowers were naturalistically portrayed. The top of the altar was painted a dull red, similar to that used as a background for the painting on the sides.

Three niches in the front or western face of the altar open at the floor level. They average 18 inches [45.7 cm] in width, 20.5 inches [52.1 cm] in height and 27.5 inches [69.8 cm] in depth; the under side of the cornice forming the tops. Each niche is formed of carefully laid wall stones which still retain traces of their original coat of bluish-gray plaster. Standing upright in each niche approximately 12 inches [31 cm] from the face of the opening is a dressed stone about 12 inches [31 cm] high. These stones are roughly rectangular and rounded at the top, and are almost identical in shape with a stone found in the inner corridor of the Caracol in 1927 [Chapter 38.13].

A cist 6 inches [15 cm] in diameter and 12 inches [31 cm] deep was found in the floor, 13.5 inches [34.3 cm] west of the altar and in line with the middle niche; a flat stone 9.5 [24.1 cm] by 11 inches [28 cm], buried half an inch [1.3 cm] beneath the well-polished lime-plaster floor, served as a cover.

Shortly after excavations were started in the inner chamber a highly unusual arrangement of dressed stones was uncovered. These formed a wall or step, one tier in height, 22 inches [55.9 cm] in width and 64 inches [1.6 m] in length. At each end of this wall, or steplike construction, there was a single rectangular block having a width equal to the wall and extending above it. To the west of this construction, at its base and abutting it, was a rectangular arrangement of vertical cornice stones having a total width of 29 inches [73.7 cm], and a length equal to that of the wall or step, itself. This construction was found some 52 inches

[1.3 m] above the altar, to which position it had settled when the arch of the inner chamber had fallen.

Subsequent excavation along the parapet surrounding the lower terrace of the Caracol revealed a small stairway directly east of this fallen steplike construction. As this small stairway has a width equal to that of this fallen construction just west of it, it seems probable that at one time both together formed a flight of steps which led from the top of the lower terrace of the Caracol upward to the roof of the West Annex. The roof of the latter must have been approximately 5 feet [1.5 m] above the top of this lower terrace.

Encased within the hearting of the platform of the West Annex was found an earlier platform which is intact except for its southwest corner. The present south face of the platform seems to be merely a western extension of the south face of this earlier platform, which measures 32 feet 5 inches [9.9 m] by 32 feet 3 inches [9.8 m] and is finished with a 9 inch [23 cm] vertical cornice.

Shortly before the close of the season the stairway of this earlier platform was discovered against the middle of the western side; it is 9 feet 3 inches [2.8 m] in width, including the plain balustrades. Due to lack of time, only the three upper steps were uncovered.

Repair of the West Annex has been completed. A section of the wall of the south platform has been left unfaced to allow for the removal of dirt, when excavation of the buried stairway is undertaken.

III. THE SOUTH ANNEX

The South Annex is the group of low-lying structures at the south base of the lower platform of the Caracol. This group was only partially excavated during the current season, sufficient, however, to disclose a complicated series of colonnaded halls and chambers. As yet the western limit of the group has not been established. The north wall of the section excavated was built against the batter of the lower platform of the Caracol. The eastern wall is 44 inches [1.12 m] west of the southeast corner of the same platform. The east face of the South Annex rises with a batter to a height of 38 inches [96.5 cm] on which rests an 8 inch [20.3 cm] battered cornice. This wall extends south a distance of 35 feet 7 inches [10.8 m], where it abuts the western base of an arched gateway, which is 13 feet 9 inches [4.2 m] long and 7 feet 2 inches [2.2 m] wide. The arch and wall stones had been painted red. The gateway and adjoining areas to the north and south are paved with flagstones.

West of the gateway there is a covered colonnade, supported by two rows of round columns, which extends across the south side of the partially excavated Annex. At a distance of 29 feet 8 inches [9 m] west of

the eastern limits of the colonnade, a doorway 6 feet 3 inches [1.9 m] in width opens into a chamber measuring 38 feet 4 inches [11.7 m] by 21 feet 10 inches [6.7 m]. The corbel arched roof was supported by four round columns. Against the north wall there is an altar approximately 6.6 feet square [0.6 sq m] and 2 feet 10 inches [0.9 m] high.

There are four doorways giving out of this chamber, two in the east and two in the west wall. Those in the east wall give into two other chambers. The southern one of these is 12 feet [3.7 m] by 20 feet 7 inches [6.3 m], and built against its east wall is an altar similar in size to that found in the large outer chamber. The north chamber is 21 feet 3 inches [6.5 m] by 20 feet 1 inch [6.1 m].

Returning to the two doorways in the west wall of the outer chamber, the southern one had been closed up in ancient times with masonry fill and the northern one gives on to an as yet unexcavated area.

Occasional sculptured stones were found built into the walls. The provenience of only one seems surely established. This is incised with the U-shaped motif, found on blocks from the façade of the West Annex.

Part of a door jamb with warriors sculptured on its three visible faces was also found on the surface, before excavations were begun. Two of these figures have the head of an animal as their head-dress, and carry shields made of wooden slats, in one case the grip for the hand being clearly represented.

SUMMARY

The chronological sequence of these several structures, so far as revealed, seems to indicate that the large lower platform of the Caracol formed the first unit. Extending in front of its western base was the red lime plaster floor upon which rested the platform reached by the lower section of the lower stairway. The various changes in the construction of this stairway must await further excavation before final elucidation.

Built directly on this red-painted floor, and to the south of the stairway, was the now buried platform of the original West Annex. Later this platform was enclosed within the present platform of the West Annex, which also covers the southern end of the platform of the lower stairway leading to the first terrace of the Caracol. On top of this first unit was built the circular substructure with its partially encircling bench, found this year, and the Caracol tower. Next, the western section of the upper platform was built. This terrace had an east and west depth of approximately 22 feet [6.7 m], the northern and southern extensions of the east wall abutting the circular substructure. Finally, this latter platform was enlarged so as entirely to enclose the circular platform.

There still exists some uncertainty as to the chronological position of the small platform or altar between the double stairway leading to the upper platform. This is surely earlier than the first, or western section of the upper rectangular platform, but it may not be earlier than the circular substructure.

HARRY E. D. POLLOCK

Report on the Casa Redonda (Station 15)

YB 28:310–311, 1929

During the season of 1928, the reconnaissance work of Karl Ruppert resulted in the discovery of a circular building situated about 1 km east of the hacienda [Chapter 38.19]. With the Caracol as the center of major operations this year, it seemed advisable that some work should be carried on at this round building, in the hope of shedding further light upon structures of this character. As the building was small and appeared to be of no unusual architectural merit, it was planned that excavations should be carried on only to the extent of exposing major features of plan and construction. With this program in view, work was begun early in April and continued for three weeks, the time being divided practically equally between excavation and repair.

After felling the bush, but before any dirt was turned, the mound presented the following appearance: A pyramidal substructure, that might be either round or square, roughly 50 feet [15.2 m] in diameter, with traces of a stairway on its west side, surmounted by a circular superstructure approximately 25 feet [7.6 m] in diameter, with short stretches of cornice showing on the north and south sides, and a depression, indicating a doorway, at the west. The wall of the superstructure apparently stood to a height of 3 or 4 feet [0.9–1.2 m], and was battered; immediately above this was the cornice. Finally, the character and disposition of the debris suggested a flat roof of lime plaster supported by beams, rather than the usual corbelled arch type. No beveled roof stones were in sight.

Excavation presented no difficulties, and was accomplished by first clearing the interior of the building and subsequently laying bare the exterior wall as far as was thought necessary. Later, trenches were driven into the substructure along one side of the stairway, and a portion of the retaining wall of this was

exposed. During excavation a fair amount of corbelled arch stones and a few capstones were encountered, but, on the whole, not sufficient to justify the assumption that the building had originally carried a corbelled arch roof.

As mentioned above, the structure was not completely excavated, but the ground plan is approximately as follows: the substructure consists of a round platform 53 to 54 feet [16.2–16.5 m] in diameter at the base, and varying in height, from 11 to 13 feet [3.4–4 m], due to the fact that the ground level is lower at the rear of the building than in front. The structure faces west, where a stairway, flanked on either side by a low bench, gives access to the summit. The wall of the substructure is slightly battered. The building on this platform is also circular with an interior diameter of 23 feet [7 m] and an exterior diameter of 30 feet [9.1 m]. It is approximately concentric with the substructure, and, the base is battered to a height of three feet, with a cornice immediately above. The outer doorway is 10 feet [3.1 m] wide, having a low step 3 inches [7.6 cm] high across the front, which served as a sill, the interior floor being slightly above the level of the terrace floor outside.

Inside the building and facing the single exterior doorway, there is a wall running north and south, forming a chord across the interior. This chord subtends an arc of approximately 120 degrees with the outer doorway which is approximately in the middle of the subtended arc. The building is thus divided, so that one-third is occupied by the front chamber and two-thirds by the rear chamber.

A doorway at the middle of this partition gives access to the interior chamber, at the rear of which there is a low stone construction suggesting an altar, while, at the true center of the building, and thus also within the rear chamber, there is a small pit sunk into the floor. This pit, which measures 2 feet 8 inches [81.3 cm] across and 8 inches [20.3 cm] in depth, is duodecagonal in shape; has vertical sides made of stone, and the remains of plaster flooring at the bottom. Several pieces of obsidian and flint, a number of pot sherds and a layer of ash were found at the bottom.

Aside from this material, and an obsidian flake, found near the altar against the back wall, the building was unproductive of artifacts, although it yielded a fair number of pot sherds.

Repair was confined entirely to work of a preservative nature. Walls were strengthened and capped as they stood, a few cornice stones were replaced, and the door jambs were set up and straightened where necessary. In addition to this, a part of the north wall of the stairway was reset and capped, while two of the balustrade stones were realigned and set in mortar. The balustrade stones have probably not been returned

exactly to their original positions; further excavation of the stairway would have been necessary to determine this point definitely, but it appeared advisable to reset these stones for the present, to prevent further deterioration.

This building gives the impression that little craftsmanship went into its construction. The stone is for the most part poorly dressed, and much of it is evidently re-used material. The only sculpture found is on the balustrade stones, which are apparently re-used pieces of door jambs or pillars, and the relief is quite without meaning in its present position. The conclusion is reasonable, indeed inevitable, that this building is very late.

With the established astronomical significance of the Caracol in mind, a number of azimuths have been taken at the Casa Redonda in the hope of discovering a similar significance for this building. While some of the readings are suggestive, further observations and revision of data will be necessary before the definite astronomic function of the Casa Redonda may be regarded as proved.

J. O. KILMARTIN

Report on Information Surveys at Chichén

YB 28:312–315, 1929

The plan and purpose of the information surveys at Chichén Itzá during the 1929 field season were to bring under more direct control and observation the area to the south of the central group of ruins, commonly known as Old Chichén; and to connect this area with the map of the central group surveyed by the writer in 1924.

In carrying out this survey the method used in mapping the various archaeological remains was the same as that adopted in 1924 on the survey of the central area of Chichén Itzá. The plane table was used to decided advantage and the control to support the map and hold it in position was obtained by triangulation from two measured bases in the plaza in front of the Castillo, and extended from these stations and others established on the most prominent ruins to the most distant corners of the map in each direction. Fourteen stations were established within the area mapped, the majority being flags fastened to the tops of trees.

It was necessary to wait until all surveys had been completed before attempting any triangulation on account of the density of the bush and the unknown, even approximate position of mounds, ruins or natural elevations which could be utilized as flag and observation stations. The region is devoid of conspicuous topographical features, being a rather flat limestone plain, scarcely more than a 100 feet above sea-level at its highest point in the center of the peninsula. Transit traverse for control was impractical, chiefly due to the difficulty in obtaining sufficiently trained native assistants for accurate work. Ten of the stations were occupied, while the remaining four were located by two or more angles from known stations. Even with the unsatisfactory procedure of establishing control after all sketching had been completed, the results obtained by magnetic needle for orientation, and tape and stadia for distance, are well within the limit of error demanded.

Observations on Polaris were taken and the magnetic declination determined as 6 degrees 40 minutes E. The secular variation over the 5-year period, 1924–29, amounted to 20 minutes of arc.

Positions along the center of the south edge of the map of the central area established in 1924 were used as starting points for the new work.

The general plan was to cover the territory on a grid base, lines being cut at intervals of 200 feet [61 m] in each direction, north, south, east and west, working in a circuit west, thence south, east and north, back to the point of beginning. The scale adopted, 200 feet [60.9 m] to one inch [2.5 cm] and contour interval of 5 feet [1.5 m], was the same as that used in the map of the central area, made in 1924. In order to make the survey it was necessary to cut lines through the bush to the extent of 30 miles [48.3 km].

The geodetic coordinate of the Castillo and the elevation of Dzitas, upon which the map is based, were very kindly furnished by Señor Ing. Don Pedro C. Sánchez, Director of Geographical and Climatological Studies of the Mexican Government, taken from Publication no. 8 of that bureau. A line of stadia levels was carried from Dzitas (C.F. 15. *Clavo de bronce*, 27.288 m; 80.504 feet) 20 km to the assumed datum plane at the western base of the Castillo at Chichén Itzá and to convert the elevations and contours, shown on the map to sea-level reference, 9.5 feet [2.9 m] should be added.

As a result of the survey 264 archaeological remains were definitely located and brought under observation. These may be classified according to their relative importance, and to some extent their use as well, as follows:

1. Temples having chambers of corbel arch construction in which ground plans could be worked out

from existing surface indications. Structures of this group are shown on the map by heavy black lines corresponding to their probable ground plans, and are drawn to scale, there being very little doubt as to their actual dimensions. In most cases these structures have columns, either round or square, and with very few exceptions are without sculpture.

Surprisingly satisfactory results in reconstructing the original ground-plans may often be obtained by noting the position and shape of certain stones.

Often in structures of this class the entire ground-plan may be worked out from such simple points as the position of a few cut stones in line, from stones which form right angles and from the presence of corbel arch stones, which are only found, when *in situ*, above the spring of the arch. Columns serve as the best guides in reconstructing ground-plans.

Large scale drawings of all groups in this class having columns were made and later reduced to the field scale of the base map.

2. In the second class of remains, the original structure has been so completely destroyed that it is quite impossible to reconstruct satisfactory ground-plans. A symbol denoting an elongated pyramids used to designate structures of this type on the map.
3. In the third class, which is the most numerous, are included such remains as platforms, altars, parapets and terraces. Single dashed lines are used to designate these remains. Such platforms and terraces were doubtless used by people of the humbler classes as foundations for their simple houses of poles and thatch, such as are, used today throughout Yucatán, especially in the smaller villages. There is not sufficient masonry debris on terraces of this class to indicate the former presence of stone buildings.
4. In this group are placed *chultunes* (cisterns), *sacbéob* (causeways), and stone walls, although the last are not designated on the map.

Five chultuns were located, all of which are in good condition, no new features being noted in their construction. One fairly long sacbé was followed from its beginning at the southwest corner of the Monjas to its terminus at the Temple of the Four Lintels. These two structures date from 1019 and 1014 AD, respectively, exactly five years difference in age. It is not straight, as had first been supposed, but follows a somewhat winding course, taking advantage of the topography in making easy grades and gentle curves.

Two other *sacbéob* (causeways) were followed from their points of beginning, but could not be continued to their termini, due to the fact that they were destroyed beyond possibility of identification. There were no structures in line or nearby at which these causeways might possibly have ended.

Only stone walls of considerable length and of apparently special significance have been shown on the map. No explanation can be offered at this time as

to the purpose of the hundreds of low stone walls which run apparently aimlessly from terrace to terrace, over mounds, across temples and out into flatlands, although they probably date for the most part from pre-conquest times.

It is now known that the Maya took advantage of every hill or elevation of any size on which to construct their houses and temples. Perhaps in addition to elevating their temples for ceremonial purposes, they desired to locate their dwellings away from the lowlands, which tended to gather and hold water during the rainy season and were correspondingly less healthful. The topography partly explains the concentration of construction in a general southwesterly and northeasterly axis.

The southeast portion of the area is practically devoid of constructional remains, although it contains one architectural unit of importance, the Group of the Hieroglyphic Jambes. There is no visible water supply for this group and should there be a well in the bottom of the dry cenote adjacent, it is now filled with debris.

As yet no astronomical rule has been discovered which governs the orientation of Maya structures. Observations on 20 buildings of Class I, on which definite construction lines could be determined, show that their longer axes (taken usually along the front façade) vary in azimuth from 187 degrees at the Monjas to 212 degrees 30' at the Temple of the Two Lintels, reading from the south centrally. Temples facing the east are few in number. Most of them face in a westerly direction; while a few face north; none has been found as yet facing south.

There is reason to believe that some astronomic phenomenon may have determined the orientation of Maya structures. In view of the relatively consistent orientation of so many different and widely distributed architectural units, it is hardly conceivable that the Maya were able to achieve such uniformity in orientation over such a large area without some definite rule to guide them.

The area covered by the information survey is slightly less than one square mile [2.6 sq km], being 5,200 feet [1.6 km] east and west by 4,800 feet [1.5 km] north and south.

In addition to the new survey, a revision was made of the major groups of the map of the central area, covering the progress made by the Institution during the first five years of its excavation program. This revision includes exact ground plans of the Temple of the Warriors, the Northeast Colonnade, the Temple of the Xtoloc Cenote, the Temple of the Interior Atlantean Columns, the House of the Corn Grinders, the Caracol and its Annexes, and the Temple of the Wall Panels. All of these revisions have been made on a large scale and then reduced to the scale of the large sheet. They

will appear on the new map, which will include all the data obtained both in the 1924 and 1929 surveys,

Solar observations, taken from the axis of the central doorway of the Temple of the Warriors to the southwest corner of the Temple of the Jaguars, showed the semi-diameter of the sun to bisect the horizon, the summit of the east wall of the Ball Court and the southwest corner of the Temple of the Jaguars at an azimuth of 108 degrees on April 12 at 6 hours, 21 minutes 40 seconds p.m., 90th Meridian time.

Observations on the planet Venus for heliacal setting through the west doorway of the outer corridor of the Caracol proved inconclusive, due to the smoke of burning cornfields which obscured the horizon and greatly reduced visibility. It seems probable that Venus may have set at an angle slightly north of West on or about April 18, since on June 3 the planet was observed as Morning Star at an angle of about 15 degrees north of east at two hours 45 minutes a.m.

38.23.

SYLVANUS G. MORLEY

Report of the Chichén Itzá Project

YB 30:104–108, 1931

Activities at Chichén Itzá during the 1931 field season were restricted to finishing repairs at the Caracol and Round House, to several minor excavations, to mapping and to preliminary architectural studies of the different buildings with a view to their more precise stylistic and temporal classification.

The staff, consisting of Dr. Morley in charge, Messrs. Karl Ruppert and H.E.D. Pollock, archaeologists; Mr. John S. Bolles, architect and surveyor; Mr. Gustav Strömsvik, engineer; Miss Kathryn Mackay, housekeeper and nurse; Miss Dorothy Jacobus, secretary and bookkeeper, reached Chichén Itzá early in January.

In addition to the work of the archaeological staff, investigations representing five cooperative projects were carried on at Chichén Itzá at different times during the year:

1. Dr. and Mrs. Morris Steggerda from the Institution's Department of Genetics at Cold Spring Harbor, Long Island, spent four months at Chichén Itzá in rechecking the earlier basal metabolism tests of Dr.

G. D. Williams (1927) and Dr. G. C. Shattuck (1929), in making intelligence tests, both of adults and children, in recording family histories and in securing a very complete series of anthropometric data.

2. Dr. Robert Redfield and his assistant Mr. Alfonso Villa in a cooperative ethnological project with the University of Chicago. Dr. Redfield divided his time between Mérida, where he resided, and the village of Chan Kom, southeast of Chichén Itzá, where Mr. Villa is schoolmaster. Consultations were held at Chichén Itzá from time to time on the progress of this investigation. Dr. Asael Hansen, another of Dr. Redfield's associates, went to Yucatán in August and remained there, until the end of the year.
3. Dr. Manuel J. Andrade in a cooperative linguistic project with the University of Chicago. Dr. Andrade spent the month of January at Corozal and San Antonio in British Honduras, studying the local Maya dialect; he returned to Chichén Itzá for the Chichén Itzá Conference, March 19–21, and accompanied Dr. Morley on the Yaxchilán Expedition as far as Monte Cristo in the State of Tabasco, where he left the Expedition to study the Indian dialects of that general region. He returned to Mérida before the end of April and to the United States early in May.
4. Dr. France V. Scholes in a cooperative historical project with the University of New Mexico was at Chichén Itzá for the Chichén Itzá Conference.
5. Dr. G. M. Saunders, Dr. F. H. Connell and Mr. B. L. Bennett on a continuation of the cooperative medical survey project with the Department of Tropical Medicine, School of Public Health, Harvard University. They visited Yucatán in July to study the distribution of malaria and amoebic dysentery during the rainy season.

A conference on general problems of Maya research under the chairmanship of Dr. Kidder was held at Chichén Itzá on March 19–21 attended by Dr. F. C. Cole, Dr. Robert Redfield and Dr. Manuel Andrade of the University of Chicago, Dr. France V. Scholes of the University of New Mexico, Mr. Juan Martínez of Mérida, Yucatán, Dr. Morris Steggerda of the Department of Genetics of the Carnegie Institution of Washington, and Dr. Kidder and Dr. Morley and Messrs. Ruppert, Pollock, Bolles, and Strömsvik of the Institution's Division of Historical Research. Reports were made on the ethnological investigations (Redfield), the linguistic studies (Andrade), the archive work (Scholes), native Maya manuscripts (Martínez), and on the archaeological and architectural investigations at Chichén Itzá (Morley, Ruppert, Pollock, Bolles, and Strömsvik).

In June, Señor F. Mugica was specially designated by Dr. J. M. Puig y Casauranc, the Minister of Public Education, to visit Chichén Itzá as the Institution's guest.

The repair of the Caracol under the direction of Mr. Ruppert was completed and during the last half of the year he has been engaged in preparing the final report on this important construction, excavation of which was begun in 1925 [Chapter 1.13].

Minor excavations were carried out at Chichén Itzá during the current field season, as follows: Mr. Ruppert, in digging east of the Red House, discovered that the back of the substructure of this building and the substructure of the colonnade just east of it had been the walls of a ballcourt, the sixth thus far found at Chichén Itzá. Although the rings through which the ball was thrown were not found, other diagnostic ballcourt characteristics were present: the parallel side walls (here with sloping inner faces); the three sculptured panels (at the ends and in the middle) at the bottom of the inner face of each of the two side walls; the two terminal lines of cut stone running across the floor of the court joining the inner corners of the two side walls, apparently defining with the side walls the limits of the court.

Mr. Ruppert also examined a new ballcourt 1 km east of the Group of the Thousand Columns, where the same sloping parallel side walls the terminal lines of cut stone connecting them, were also found.

Mr. Pollock at the end of the field season did further digging in the substructure of the Round House about 1 km east of the hacienda.

Finally, a building at Jalacal, some 4 km northeast of Chichén Itzá, was excavated. During the Spanish colonial period an hacienda had grown up around the cenote at Jalacal, the plantation house of which was built from cut stone taken from a small Maya site, which had also flourished around the cenote in earlier times. A hieroglyphic stone lintel, which in all probability had originally spanned a doorway in the principal temple at Jalacal, had been removed during the colonial period and had been built into the stone watering trough in front of the plantation house [Chapter 1.14], from which position it was removed to the Museum of Archaeology and History in Mérida several years ago.

Excavations were made in the mound from which the hieroglyphic lintel is supposed to have come, the most important fact established being that the temple dates from the pure Maya period, that is, it antedates the period of Mexican influence at Chichén Itzá.

During the current field season, the architectural remains at Chichén Itzá were restudied by the resident staff with a view to their more precise classification. The standing buildings were carefully studied by the staff and weekly meetings were held to discuss problems arising from these first-hand inspections and comparisons of the architectural remains.

The only surely dated object thus far found at the site is the so-called Initial Series lintel, which was dedi-

cated in 10.2.10.0.0 of the Maya Era, just before the close of the Great Period of the Old Empire. The Temple of the Initial Series, in which this lintel was reused as a wall stone [Chapter 1.14], is of much later date than 10.2.10.0.0, and since the lintel seems to have been designed for a much earlier construction the question of its original position naturally arises. Up to the present, however, no building referable to the Old Empire has been found at Chichén Itzá.

Calling this earliest and as yet unrepresented period, no. 1, let us proceed with the classification of the more important of the remaining structures (Table 38.23.1).

The architectural characteristics which serve to differentiate Period III, the so-called Period of Mexican Influence, from Period II, are clear, and unmistakable. They are: serpent columns, anthropomorphic and zoomorphic Atlantean columns, square and round columns (both plain and sculptured), colonnades, battered wall bases, roof crests, serpent balustrades, chac mool figures, Atlantean figures, Tlaloc incensarios.

Those few structures, which have been placed in a transitional group between Periods II and III, are doubtful only because they present features characteristic of both Periods II and III. Perhaps the best example of this doubtful group is the Caracol, which, in addition to a number of pure Maya features (Period II) has serpent balustrades, roof-crests and Tlaloc incensarios all characteristic of Period III. It will be noted in this connection, however, that all of these Period III elements are of such a nature, decorative rather than structural in function, that they may well have been added to a Period II building in Period III times, in order to bring the exterior of the earlier building into harmony with the style of architectural decoration used in Period III, that is, that they represent a Period III endeavor to modernize a Period II building.

Even buildings as essentially characteristic of Period II as the Red House and the Temple of the Four Lintels show definite remodeling in Period III, as if there had been an attempt, so to speak, to bring them up to date. Both on the roof of the former and directly in front of the latter, in which position it had clearly fallen from the roof, roof-crest elements were found. It is therefore unnecessary to assume that all Period II buildings were abandoned in Period III; almost certainly such was not the case.

As yet no structure surely referable to the hypothetical Period I, that is, the period of the Initial Series lintel, has been found, but it is not improbable that further study of the architectural remains may result in the identification of buildings belonging to this period. The ceramic studies now being carried on at Chichén Itzá by Mr. H. B. Roberts should shed much

light on the location of the first Old Empire occupation of this site.

The preliminary classification of the architectural remains at Chichén Itzá, undertaken during the current field season, has already indicated promising lines for further investigation, especially in connection with the ceramic sequence, and it is planned to continue these studies during the next field season.

38.24.

KARL RUPPERT
The Caracol

YB 30:108–109, 1931

Chichén Itzá, as one of the large centers of the Maya New Empire, readily lends itself to an intensive program for archaeological investigation. Dating from the close of the Old Empire and showing within its precincts extensive influences of the late Nahua incursion, its remains must of necessity offer a productive field for the archaeologist. An analysis of the mounds, terraces, buildings, sculptures, and artifacts is the problem presented.

First and foremost in attacking the problem, a type structure of each period should be examined and studied. As yet no construction has been found dating from the Early Period of the city's history, the single dated object therefrom being the door lintel which was reused in the Temple of the Initial Series. From the Middle Period, 1000 to 1200 AD, such structures as the Temple of the Three Lintels, the Akabtzip, Monjas, and Casa Colorada are representative types. The late Period, that of the Nahua, is exemplified by the Castillo, Temple of the Warriors, Ball Court and the Group of the Thousand Columns.

If a type structure for each period is to be studied, so also must an effort be made for the preservation of such type structures. Thus there has developed an aspect of the work which in some cases is more time consuming than the excavation itself.

Of the Chichén Itzá Middle Period, the several structures above enumerated were found in relatively good condition and could be studied without excavation. Hence, first attention was directed to the Temple of the Warriors, a representative of the Late or Nahua Period. The investigation and repair of this building, which were accomplished during four field seasons under the supervision of Mr. Morris, have thrown much new light on the last phase of the Nahua Period.

Between the close of the Middle Period and the springing of the Nahua style into full bloom, there may be expected to have been a time of transition, study of which is obviously most desirable for comparative purposes.

The Caracol, the second structure that has engaged the attention of the Chichén Itzá project, gave promise of representing such a transition. Its location in a quarter of the city in which all the other important structures are of the Middle Period has been an added incentive for its investigation. The building is also of unusual interest in that it represents by far the finest

and best-preserved of the comparatively few round structures in the Maya area. Furthermore, the deep windows in the upper part of the tower which have orientations of west, southwest and south, have long led to the supposition that this was an astronomical observatory.

In 1925, Mr. Ricketson undertook the very imperative repair of the three remaining windows and the strengthening of a section of the southeast outer wall and arch which was in a state near collapse. During the 1926 field season, Mr. J. Eric Thompson was in charge of the work of repairing stairway, clearing a section of the upper terrace and starting the laborious task of replacing the 5-member cornice of the tower, the only such cornice known in the Maya area.

Subsequent years, with the exception of 1928, were devoted to the complete excavation and repair of the structure. From a great mass of fallen stone with only a portion of the tower jutting skyward, there has now emerged a large rectangular terrace supporting a second, each with its broad stairways flanked by balustrades of intertwined serpents. Surmounting the upper terrace is the round tower with its two concentric rooms and the circular stairway built into the great mass of masonry which forms the central core. The stairway leads to a small chamber in the top of the tower from which open the horizontal shafts or windows which are thought to have served for observing astronomical phenomena.

Excavations have shown that time after time the plans were changed during the course of construction of the Caracol complex. The stairway of the lower platform was enlarged and serpent balustrades added. Two platforms, one within the other, and the later one surmounted by a colonnaded temple were built to the south of the lower stairway and against the lower platform. Originally rising from the main platform was a large circular structure of solid masonry. Barely completed, it was encased within second circular structure, the western half of which was in turn concealed by a rectangular platform carrying a broad stairway. This final addition was then extended eastward to form the great rectangular terrace from which rose the Caracol.

The Caracol, a complex so extremely specialized in form and the only one of its type at Chichén Itzá, except for the Casa Redonda, a very crude round building recently discovered a kilometer to the east, must of necessity have played an important part in the life of the city. As one of the larger structures and occupying an important position in a precinct containing a majority of buildings of the Middle Period, its development and architecture are significant. The story read in the excavations is one of indecision, change and quick building sequence. The unspecialized arch stones, sculptured hieroglyphs, stone lintels and sub-

structure with rough stone facing are indicative of the Middle Period. The elaborate stone roof ornaments and stone incensarios belonging to the Nahua Period may well have been added to bring an early structure into conformity with a later style.

Much work yet remains to be done before the problems raised by the Caracol can finally be settled. For a better determination of the period to which the structure belongs, a series of trenches between it and the Monjas; Akabtzip and Casa Colorada should prove helpful. A detailed study of sculptured material, especially of the mask decorations should be undertaken. Relationships between the Monjas or other definitely known early structures and between the Caracol and later structures may well be developed.

To date, the Caracol and the Casa Redonda, both at Chichén Itzá, are the only round buildings in the Maya area that have been excavated. An examination of similar structures which exists at Mayapán, Paal Mul, Orthindzonot and Muyil should be undertaken. Analytical comparison should lead to better understanding of their position in the architectural history of Yucatán, and perhaps shed further light on the function of the Caracol.

38.25.

ALFRED V. KIDDER

Chichén Itzá

YB 31:92–95, 1932

The work at Chichén Itzá, under direction of Dr. Morley, consisted of the excavation by Mr. Karl Ruppert of the Mercado, one of the largest Nahua-period buildings in the city; and the study by Mr. John S. Bolles of a highly important Maya Period structure, the Monjas.

The Mercado (English, market-place); the name is a local one which probably has no significance, (the structure having doubtless been erected for purely ceremonial purposes) forms the southern element of the great quadrangle known as the Court of the Thousand Columns, a plaza-like area of some 6.5 acres [0.03 sq km] surrounded by colonnades and temples, the largest of which, the Temple of the Warriors, was excavated and repaired during the years 1925 to 1928 inclusive Chapters 38.3, 38.4, 38.10, 38.11, 38.15, and 38.17; Morris, Charlott, and Morris 1931).

The Mercado proved, upon investigation, to have consisted of a single vaulted chamber no less than 250

feet [76 m] in length, fronting upon the open expanse of the Court of the Columns, and communicating, by a doorway in the middle of its back wall, with a cloistered enclosure of rectangular form. Several ruined buildings, apparently very similar in plan and, therefore, presumably alike in function, have been identified by Mr. Ruppert in other parts of Chichén Itzá, but the Mercado, like most of the structures in the northern group, is conceived on a much more grandiose scale than the other examples of its type. The single vault, for example, is nearly 15 feet [4.6 m] wide, the broadest span yet recorded from the Maya area; its cap-stones are unprecedentedly large and heavy; the 37 alternating round and square stone columns which supported it on the front, and rendered it, in effect, a vast portico, are impressively massive. The architect of the Mercado was, it would seem, a man of bold ideas and much technical daring. But his creation held the weaknesses common to all Maya buildings; in particular it suffered from over-reliance upon inter-columnar beams of wood to carry the colossal load of the superstructure; and there is evidence that it crashed into ruin even before the abandonment of the city. Its fall, however, had covered in perfect preservation an altar, on which was sculptured in relief, and brilliantly painted, a procession of elaborately costumed captives, roped hand-to-hand, marching from either side toward a central enthroned figure.

The rear court is 130 feet square [12.1 square m]. It was surrounded by a cloister of slender, round columns 15 feet [4.6 m] high, which bore a flat, probably thatched, roof.

Excavation of the Mercado brought the usual grist of problems. Such an undertaking involves two sets of objectives: archaeological and preservational. For the purposes of archaeology one seeks to derive every possible scrap of information regarding any given building: its ground plan and elevation, its decoration, the technical details of its architecture; one must attempt to learn its temporal relation to other buildings, to understand its function; and during the work one must gather all the collateral evidence that may be present in the form of pottery, implements, paintings, sculpture and whatnot which bear upon the material and esthetic development of the ancient people. To collect the above data requires the most careful digging and the most intelligent and meticulous recording. These processes may perfectly well be carried out with no concern for the ultimate preservation of the structure itself. But the observations of the original investigator may be faulty; or he may overlook points of one sort or another which subsequent study prove to be of importance. Hence it is imperative that he leave the building in such condition that re-examination, by himself or others, is feasible. In some cases he can cover up what

he has cleared, thereby saving it from further disintegration. Often this is the best method. But at a site as outstanding as is Chichén Itzá, visited by many archaeologists and great numbers of laymen, it becomes essential to leave all major structures visible, understandable and sightly.

The preservation of an excavated Maya temple is a difficult matter. One must hold in their original position all elements found standing. To do this often requires extensive repair of weakened supports. Then there is the problem of how much that is fallen should be replaced. As a rule there are many parts of a building that lie, stone for stone, as they collapsed. There can be no shred of doubt regarding their former position. Should they be put back? There is always a strong temptation to do so, not only to render the structure more easily comprehensible, and because the scattered elements, if left on the ground, are exposed to all sorts of hazards; but also because one feels a duty, well expressed by Dr. Breasted during his recent visit to Chichén Itzá, to "fulfill one's obligation to the memory of the ancient architect." But restoration, once begun, is hard to stop; one move leads to another, with danger of error, with risk of destroying the psychological effect of a realization of time and change, inherent in a ruined building. To say nothing of the expense.

At Chichén Itzá, Dr. Morley and his staff have very wisely governed themselves by circumstances. They have applied different methods to different units. Some temples, as the Xtoloc, have been held exactly as cleared; others, like the Warriors, have been rebuilt as far as there was absolute evidence for every step; one small one, the Temple of the Three Lintels, of which practically every stone was recovered, they restored completely. The Mercado might perfectly well have been put back almost block for block. Enough remained standing, however, to make it readily comprehensible. Decision was therefore made to hold it as nearly as possible in the condition in which it was found; certain columns of the portico were straightened; those in the cloister had fallen, so half of them were re-erected, the remainder cleared and left lying, drum by drum, as they had crashed; the main wall was strengthened and stairways, skewed and warped by tree-roots, were aligned and solidified.

The other major undertaking at Chichén Itzá during the 1932 season was the study, by Mr. John S. Bolles, of the Monjas, the largest and most complex of the few purely Maya temples erected at the site before the coming of Mexican influence stimulated the great building "boom" of later times. The Monjas, like the Mercado, bears a modern name, meaning in English "Nunnery," because of its many cell-like chambers. The use, however, to which it and many similar buildings, throughout the Maya area were put, remains problematical.

This particular exemplification of the "Nunnery" or, as it is sometimes called, the "Palace" type is archaeologically most important because it gives evidence of manifold remodelings and enlargements, no less than five distinct periods of architectural modification being evident, even on superficial examination.

The architectural problems of the Monjas can not be made clear without many diagrams and sections. Many points, indeed, are not yet understood. It suffices, therefore, to say that, over and about an originally small building, there were erected a series of later ones, each larger than its predecessor; and that during the whole long process of growth there were tearings down, alterations, additions against and upon and around, the result of which is a veritable puzzle in massive masonry. But its very complexity gives the Monjas its significance, for it offers a most perfect case of architectural stratification, providing opportunity to recover irrefutable data upon the sequence of building processes and the devices of ornamentation.

Mr. Bolles naturally attacked the Monjas with due caution. He began his work by digging about the substructure of the latest increment in order to learn its relation to the many small ruins which lie close about it. This resulted, as seems always to be the case in Maya excavation, in the uncovering of a perfect mare's-nest of platforms and razed buildings, including the remains of a very large Nahua ball-court and of a whole series of late temples. Into the substructure of the Monjas two tunnels were driven, following the walls of an annex which disappears within it and whose relation to the main mass has not been understood. This mining operation served to trace the annex toward its original abutment against an inner substructure and to explain certain essential features of the growth of the whole complex. But the investigation has only just begun and, as is again always the case in Maya excavation, the problem at this stage has become far more involved than it seemed before work was started.

The question of the ultimate state in which the building is to be left is, however, a perfectly simple one. The Monjas is in relatively perfect condition, stands free of debris, its principal features are comprehensible without any restoration. Furthermore, it is a very beautiful ruin. Therefore it is obvious that it should be held in exactly the same condition in which it appears today. This is, as has been said, a simple matter, in principle. In practice it is far from easy, for it is much harder to solidify and keep from further disintegration a warped wall or the tottering blocks of a partly wrecked stairway, than it is to take them down and relay them. Such, nevertheless, must and will be done. The work of preservation was inaugurated this year by a difficult piece of emergency strengthening made necessary by two great caverns in the western part of

the substructure, which seriously endangered the whole Monjas. These, with greatly appreciated financial cooperation on the part of the Mexican Government, were solidly filled, passages being left open to permit observation of buried structures and to serve as points of departure for new exploratory tunnels.

Other activities at Chichén Itzá were the partial clearing by Mr. Ruppert of an interesting group of small temples discovered by him in the dense bush to the east of the Court of the Columns; and the commencement, by Mr. Strömsvik, of a highly promising comparative and analytical study of serpent columns. Dr. Hermann Beyer, whose services were most generously lent by the Department of Middle American Research of Tulane University, through courtesy of its Director, Mr. Frans Blom, spent several weeks at Chichén Itzá in a meticulously thorough examination of all the hieroglyphic material in the city. To three volunteer workers the Institution is indebted for extremely valuable services. Mr. John P. O'Neill surveyed the area in the north-western quarter of the city necessary for completion of the topographic map of Chichén Itzá; he also mapped the Mercado and began detailed drawings of the mask-decorations of the Monjas. Mr. J. H. Denison, Jr., made rubbings of many inscriptions, developing a new and very satisfactory method for the recording of glyphs. Mr. W. L. Lincoln, who was at Chichén Itzá during the entire season, surveyed, made the color record of the painted altar in the Mercado, mapped the ruins of Yaxuná, and conducted an expedition to Yaxhá in the Department of the Petén, Guatemala, where he prepared a map of the site for Dr. Morley's forthcoming monograph on the inscriptions of Petén. Dr. Morley, in addition to his duties as Director of the Chichén Itzá Project, brought the above-mentioned monograph, the product of 20 years of exploration and study, to a stage verging on completion.

Throughout the season the staff were kept in touch, through the courtesy of Sr. Eduardo Martínez Cantón, with his very important and spectacular finds in the excavations of the Mexican Government at the Castillo.

38.26.

ALFRED V. KIDDER
Archaeological Research

YB 32:83, 1933

The work at Chichén Itzá, under direction of Dr. Morley, consisted of excavations by Mr. John S. Bolles at the

Monjas; repair of the Temple of the Phalli by Mr. Gustav Strömsvik; and continuation of Mr. H. B. Roberts' ceramic studies. Mr. John O'Neill and Mr. Strömsvik also remapped the nearby ruins of Yaxuná; and Sr. Alfonso Villa made the first traverse of the ancient highway which connects the cities of Yaxuná and Cobá. The Institution's station at Chichén Itzá served, as usual, as headquarters for collaborating investigators and as base for the Campeche expedition.

38.27.

JOHN S. BOLLES

Excavations at the Monjas

YB 32:84–86, 1933

The Casa de las Monjas (House of the Nuns), so called because of its cell-like chambers, is one of the best-preserved structures at Chichén; archaeologically it is probably the most important building in the city. Hence its investigation, begun in 1932 and carried to virtual completion during the current year, demanded very thorough planning and most careful execution, in order that the search for scientific information should not lead to loss of esthetic values. This was a particularly difficult task, because the Monjas owes its significance to the fact that it underwent many rebuildings and almost countless alterations: removal or covering up of earlier elements, addition of wings, changes in plan, elevation and decoration; all of which have resulted in producing a veritable puzzle in massive yet treacherously insecure masonry. It was naturally desired to recover as much information as possible regarding the nature and sequence of the various structural increments; but some of these had been so nearly obliterated that there remained only the slightest traces of their former presence, and others were deeply buried under later construction. To have begun at the outside and to have studied and removed the increments one by one would, of course, have been a relatively simple procedure. The Monjas, however, is among the finest of Maya temples. It was therefore imperative that excavation should not mar in any way the great beauty of its present semi-ruined condition. Furthermore, our knowledge of Maya architecture is not yet sufficiently complete to guarantee that we will not overlook phenomena of importance to future students. So no part of the building could safely be removed; and Mr. Bolles

and his associates, were accordingly forced to exercise the greatest ingenuity in trenching, pitting and tunneling. How well their work was done can only become apparent when it is fully published. The Monjas, as they have left it, gives no indication that it has been so deeply and so thoroughly probed.

Such a report as this does not permit the inclusion of the many drawings and photographs necessary to make clear even the general structural history of the building; to say nothing of its many highly significant details. A brief summary of the work must therefore suffice.

The investigation had two phases: excavation and study of the building complex, and its repair and consolidation. Replacement of fallen parts was undertaken only where necessary for the preservation of standing elements and then only when there was definite evidence to justify such procedure. There were times when repairs had to wait until certain excavations were completed; excavations were often delayed for repairs.

Search was made for evidence bearing on the nature, extent and interrelation of the terraces underlying and surrounding the building proper. This required a great number of relatively shallow trenches and pits, all of which were ultimately refilled. They resulted in defining the limits of certain terraces; others, largely or wholly removed during alterations to the complex, could only partially be run out. It was a very difficult matter to hold the exterior trenching within bounds, as there was constant temptation to follow interesting and possibly important leads, which, however, were certain to involve the excavators in problems of other nearby buildings not immediately pertinent to study of the Monjas.

All Maya temples were erected upon basal platforms. The site of the Monjas bore several successive temples, each one larger and higher set than its predecessor. Hence there now exists a series of basal platforms, one within the other, some of which can be examined at places where they have been exposed by the caving of later masonry. To secure information as to others and to study the buried faces of all, it was necessary to tunnel, both vertically and horizontally, through many meters of loosely piled rock fill, a costly and often dangerous procedure. Data, however, were recovered upon the size and method of construction of the platforms; it was also determined that none of the earlier temples is still extant.

Concurrently with the architectural study of the latest building with its annexes and wings, there was carried forward the work of repair and repointing. From their footings to their crowning friezes of stone-mosaic masks the platforms were carefully gone over, and every room of the building was checked from floor to

vault peak and roof. The broken west end was given a new facing of rough stone, as nearly as possible like the old end that was continuing to break away in great sections. This type of work will delay for years the collapse of the Monjas. The Iglesia and the Southeast Annex were also given the same thorough going over. Throughout the work, every effort was made to preserve the charm of the Monjas as a ruined Maya edifice and to hold intact all the work of the original builders. Floor levels and wall lines were carefully saved, for no matter how careful the excavation or how minute the observations, something is bound to be overlooked or something destroyed that may later be of infinite value as more is known of the Maya and their construction methods.

The great two-flight stairway, which gives access to the upper buildings, was found to be in exceedingly bad condition. Removal of debris west of the lower flight showed that insecure footings had led to the development of a crack so serious as to threaten collapse of the entire west face of the stairway. This necessitated very extensive repair, including the introduction of sound new footings and the binding of the crack by means of concealed iron rails with bent-down ends. The undertaking was a hazardous one, as hundreds of tons of stone were in imminent danger of falling. A section of the stairs did, indeed, give way, painfully injuring Mr. Bolles and narrowly missing killing him. Photographs taken before the repair began permitted exact replacement of the steps that had come down. The second-story stairs were also jeopardized by the weakened condition of the supporting platform and had to be removed and rebuilt along with the dangerous section of platform. Again, photographs were used to insure accurate resetting of all stones in their former positions.

One of the most important aspects of the investigation was the making by Mr. R. T. Smith, of measured drawings of the many masks which embellish the Monjas. These masks, huge and grotesque conventionalized faces, are, in essence, mosaics of cut-stone, the dozens of individual pieces tenoned into a masonry backing. Such mask formed one of the principal decorative elements of Maya architecture. They varied both locally and chronologically and so constitute a potentially most useful criterion for the classification of buildings. Mr. Smith's drawings set a standard of accuracy heretofore unattained. Their analysis will form the basis for the careful comparative study of masks which will eventually have to be made.

Mr. F. P. Parris, of the University of Pennsylvania Piedras Negras Expedition, joined Mr. Bolles toward the close of the season. His drawings of the seven carved panels of the ballcourt south of the Monjas show every detail of design and every variation of curve.

No more accurate rendition of low-relief sculpture could be made.

38.28.

GUSTAV STRÖMSVIK

Temple of the Phalli

YB 32:86, 1933

In 1926 investigations were made by G. C. Vaillant and J.E.S. Thompson at the Group of the Initial Series in "Old Chichén." The Temple of the Initial Series, the Temple of the Little Heads and the Temple of the Atlantean Columns were completely excavated [Chapter 38.9]. Exploratory work was also done at the nearby Temple of the Phalli, which indicated that a thorough examination of that building and its many annexes would constitute a project too large to be undertaken at that time. During the years between 1926 and 1933 it was hoped to reopen operations at this very important temple. But as it is now evident that renewal of activity in Old Chichén must still further be postponed, it was decided to fill the old excavations and to carry out certain repairs which would guarantee the structure against deterioration. These tasks were accomplished during the past field season. The complex of courts and colonnades was cleared of unworked stone, sculptured elements were assembled, columns were re-created, and walls were repaired and capped. The capping of walls unprotected by roofs is accomplished in the following manner: All faced wallstones, which threaten to lose their hold, are numbered and taken down. Then the root-riven mortar of the wall's core is worked out until solid ancient masonry is exposed. The core is built anew with fresh materials and the original veneer of faced stones is replaced, each block going back to its exact former position. Finally, a capping of spalls and mortar is laid along the wall top. This is made high in the center to facilitate drainage and to prevent lodgment of earth in which vegetation might gain a footing with consequent damage by the wedging action of roots.

The roofed chambers of the Temple of the Phalli were cleared of debris, walls were strengthened where necessary; and new wooden lintels, replacing ancient lintels now rotted away, were introduced over certain doorways and reinforced by hidden steel rails. The roof of the building also received such attention as

was necessary to prevent leakage with consequent damage to the cores of the walls. This important and interesting structure is now in such condition that, if it be kept clear of bushes and trees, it will stand for many years.

38.29.

SYLVANUS G. MORLEY, KARL RUPPERT, AND JOHN S. BOLLES
Chichén Itzá

YB 33:89–90, 1934

The excavations at Chichén Itzá during the 10 years covered by the first permit granted to Carnegie Institution by the government of Mexico have resulted in accumulation of a great amount of information as to the architecture and ceramics of that site. As always, the process of gathering and recording facts has gone faster than that of digesting and publishing them. Hence it seemed best to undertake no new excavation projects in 1934, nor to plan any large-scale undertakings for the immediate future. This policy has been adopted because time is required to prepare reports on work already done. But of even greater importance is the need for a pause in local research to permit investigation of problems raised at Chichén, whose solution requires evidence from other sites. These problems will be discussed after the work of the current year has been noted.

The first aim, of the Mexican government and of Carnegie Institution in the work they have been carrying on at Chichén Itzá has been, by excavation of buried structures and by study of those still standing, to learn as much as possible regarding the history of the city and as to Maya architectural practice. Concurrent objectives have been: strengthening and repair, to keep the temples from further disintegration; and, when it could be done with assurance of accuracy, replacement of fallen elements for the purpose of rendering the buildings more easily understandable to the many persons who visit this outstanding and most readily accessible of New Empire centers.

The Mexican government has devoted its efforts to the Great Castillo-Ball Court Group, the culminating achievement of the Nahua period. Carnegie Institution has occupied itself with three sequent phases of

Chichén architecture: Late Nahua (Temple of the Warriors, Mercado, and various lesser structures); Early Nahua (Caracol); and Pure Maya (Temple of Three Lintels, Monjas).

38.30.

KARL RUPPERT
Mercado

YB 33:90, 1934

During the season of 1934 a small amount of excavation and repair was done at the Mercado [Chapter 38.25], which now requires very little further work. In center of the cloistered rear court, there came to light what seems to be a dedicatory cache of carved jades and other cult objects, ensconced in a buried block of masonry.

38.31.

JOHN S. BOLLES
Monjas

YB 33:90–91, 1934

The major archaeological activity at Chichén was completion of the intensive study of the Monjas, the most interesting architecturally and perhaps the most significant historically of all the buildings at Chichén Itzá. Mr. J. S. Bolles, who has been in charge of this work since its inception in 1932 was, as in 1933, assisted by Mr. T. R. Smith.

The first element of the structure was erected in the very early days of the city, while pure Maya architecture was in full vogue. While this style still remained unadulterated, it grew by successive additions to great size. Through the Nahua period it continued in use; and it was not abandoned until temple-building ceased at Chichén at, or very shortly before, the Spanish Conquest. Its final increments, indeed, are probably among the latest of all aboriginal constructions in the penin-

sula. The Monjas evidently fulfilled some function vital to the ceremonial life of the city, for it was added to or altered during every period. That such a long span of time is represented in the elements of a single building complex renders the Monjas a veritable mine of information as to successive types of architecture; and its wealth of varying structural features and of ornamental detail makes possible its relation both to classic Maya temples and to those of the later eras.

The Monjas has been briefly described in earlier reports [Chapters 38.25 and 38.27]; and it will be treated at length in Mr. Bolles' forthcoming publication. The activities of the past year consisted in finishing the repairs, in order that the building might be left in the best possible condition to resist further deterioration; in checking doubtful points as to the relation to each other of various structural increments; and in preparation of notes, plans and elevations for in the final report. This monograph should be of unusual interest, not only because of the great archaeological importance of the Monjas, but also because the excavations have been from their inception in the hands of men specially trained in architecture. In Europe and the Near East, the investigation of monumental architectural remains has habitually been entrusted to architects; but the present undertaking is one of the first in America to be so handled.

38.32.

SYLVANUS G. MORLEY

Chichén Itzá

YB 35:120–122, 1936

Dr. Morley was in Yucatán from September 1935 to August 1936, engaged in completion of his monograph upon the inscriptions of Petén. He also devoted much time to forwarding the work of the various collateral investigations based upon Chichén: the Campeche-Quintana Roo Expedition, the Ceramic-Architectural Survey, the ethnological survey, the anthropometric and other studies of Dr. Steggerda, and the documentary research of Messrs. Roys and Rubio Mañé. Likewise using Chichén as headquarters were an ornithological party from the University of Michigan (Dr. van Tyne and Dr. Trautman) and a biological party from Duke University (Dr. Pearse and Dr. Hall).

Dr. Morley was at Sotutá and Yaxcaba for a week in the middle of December 1935 in connection with his genealogical investigation of the former ruling houses of the Yucatán peninsula. Sotutá was the seat of the Cocóm, the ancient lords of Mayapán, during the Spanish colonial period and additional data concerning Cocóm family history were sought there he visited X-Cacal for a week at the beginning of March, on the occasion of the festival to the Virgin of the Conception, one of the two most important events of the ceremonial year among the X-Cacal Maya. Dr. Morley's party was handsomely entertained, and in addition to strengthening the bonds of friendship already established between these semi-independent Indians and the Institution's representatives in Yucatán (upon which Mr. Villa's continued residence among this remote and highly suspicious group entirely depends), Mrs. Morley secured an exceptionally fine series of photographs of representative types of men, women and children and of the ceremonies witnessed.

J. Ignacio Rubio Mañé continued his documentary investigation under the direction of Dr. Morley and Mr. Scholes. He made occasional trips to outlying towns and villages to examine church records in connection with a study of the Xiu, Cocóm, and Pech families. The larger part of his time was spent in Mérida, where he searched ecclesiastical, governmental and private archives for information concerning the growth of the church properties, and upon the development of the haciendas and their relation, if any, to the earlier encomiendas.

Mr. Rubio Mañé succeeded in relocating the so-called Códice Pérez, which contains copies of earlier Maya manuscripts made by the eminent Yucatecan antiquarian, Don Pío Pérez, about the middle of the last century, and which heretofore has been known only through the Karl Berendt copy of 1866, in the Museum of the University of Pennsylvania, and a later copy by Ermilo Solís Alcalá of Mérida about a decade ago, both containing a number of errors. Perhaps the chief importance of the Códice Pérez lies in the fact that it contains the only known copy of the Book of Chilam Balam of Maní, the original of which is now lost or more probably was destroyed in the War of the Castes in 1846–47. This latter, in turn, contains one of the only five chronicles of pre-Columbian Maya history that have come down to us. Permission to photograph and publish this exceedingly valuable manuscript was secured from the owner. The photographic reproduction is now being studied by Ralph Roys who will eventually undertake the preparation of an annotated translation.

Another manuscript photographed for Mr. Roys this year was loaned to Alfonso Villa at Tusik by one of the X-Cacal Maya. This consists of two parts; a legend

of a hunter and a deer; and, more important, a series of questions put to candidates for chieftainship. It is similar to the questionnaire given in the Book of Chilam Balam of Chumayel, already translated by Roys. Although the X-Cacal copy of this text was made at Santa Cruz Bravo only 61 years ago (1875) a colophon indicates that the original from which it was copied was reduced to writing in 1628.

Karl Ruppert reached Chichén Itzá on January 21. He spent the months of February and March in writing a report on his excavations of previous years at the Mercado. In April Mr. Ruppert, assisted by Mr. P. N. Fontaine as consulting architect, commenced the excavation of the small structure just east of the large temple on the east side of the court of the Thousand Columns. The building is of unusual ground plan, being composed of a portico with columns along the front or outer side, a smaller chamber behind, and a still smaller niche at the back where a secondary fireplace was found. The only similar construction, known at Chichén Itzá, is one just south of the Caracol which was excavated by Ruppert in 1929. Interior arrangements of both, buildings strongly suggest that they served as vapor baths, special buildings for which purpose, the *temezcalli*, are known to have been used by culturally not dissimilar peoples of the highlands of central Mexico in the early sixteenth century, and which indeed still survive in the latter region. The excavation and repair of this building were made possible by the generosity of the Misses Amelia E. and Martha White of Cocoanut Grove, Florida.

38.33.

SYLVANUS G. MORLEY

Chichén Itzá

YB 36:139–141, 1937

Mr. Karl Ruppert spent six months at Chichén Itzá gathering data for an evaluation of Nahua influence upon the architecture of that city, and for a report on such structures as have, wholly or in part, been excavated and for which there is no published record. A survey and analysis of the Nahua structures presupposes a knowledge of the Maya buildings at the site. This survey is to be purely local and such facts as may be determined will apply only to Chichén Itzá and here, of course, will be true only as far as present excavations have been conducted and surface examina-

tions extended. Certain architectural features such as serpent columns have come to be identified as definitely Nahua; thus buildings in which these are utilized in key constructions must be considered as of the late period. Late concepts appear in early structures only where they have been added as roof ornaments or other superficial decorations, never as fundamental elements of construction.

The survey has included the examination of eight ballcourts. Seven, in which stone rings have not been found, have benches one-third or less the length of the largest court. All are apparently of the late period and show great differences in slope of face and top of bench. The main walls, however, seem to rise vertically. Because of the extreme variation of the courts it is evident that the game could not have been standardized; and the possibility of its having been played in the single enormously large court, may, in Mr. Ruppert's opinion, perhaps even be questioned.

The plans of structures in the two periods show little in common. The two-chambered temple resting on a lofty pyramid and now encased within the Castillo is, if correctly interpreted, the only example of such a structure in Maya times. Buildings of the palace type are not associated with the Nahua. The shrine room, which is not represented here in the Maya period but is found in their cities to the south, was developed and elaborated by the late people of Chichén Itzá. Arrangements of colonnades of one to four vaults in depth, colonnades and temples, and cloisters appear that do not have counterparts in early structures.

Carved stone was the medium used for building ornamentation during both periods, and practically all motifs are carried from early to late times façades in both periods, except for two- and three-member moldings, may be plain. If ornamented, those of the Maya showed a tendency toward over-all decoration, while the Nahua more consistently simplified the treatment by the use of alternate plain and sculptured panels. Realistic bas-relief was not attempted by the Maya.

Differences are noted in the manner of cutting, dressing, and laying stones, and in late times stones of the vault were highly specialized. The floor level of the inner chamber is placed a step up from that of the outer chamber—a common Maya feature which is not seen in unquestioned Nahua structures. Numerous minor but evidently nonetheless significant differences in construction, developed or brought in by the Nahua, become apparent as the material is analyzed.

Dr. Morris Steggerda, accompanied by Dr. T. J. Hill, of the Institute of Pathology of Western Reserve University, reached Chichén Itzá early in February, the former remaining for two months, the latter for a month. Dr. Steggerda continued his study of the local Maya, whose anthropometry, ethnology, sociology,

psychology, genetics, and economic life he has been investigating for the past six years. Dr. Hill examined the dentition and saliva of the Maya, taking specimens of the latter for further study in the United States.

Mr. Ralph Roys made his headquarters at Chichén Itzá from the middle of February to the end of March. He identified a number of points on the frontier between the ancient provinces of the Cupules and the Cocoms, mentioned in the Ebtún Papers of which his annotated translation is being prepared for press.

Dr. S. A. Barrett, Director of the Public Museum of Milwaukee, accompanied by Mr. George Peter, of the museum staff, spent the month of April at Chichén Itzá collecting data, photographs, paintings, drawings, and descriptions for the construction of six groups at the museum illustrating various phases of ancient life at Chichén Itzá.

Dr. Josselyn Van Tyne, of the Museums of the University of Michigan, was at Chichén Itzá during July and August collecting birds. Last year he made a similar collection during the dry season (March and April) and with the specimens secured this year it is possible to describe the avifauna of the region throughout the year.

On the return trip from Copán to Chichén Itzá early in March, Dr. Morley visited the canal just north of Puerto Barrios, Guatemala, where the Leyden Plate was found about three-quarters of a century ago, and also flew over the ruins of Yaxhá, Uaxactún, Tikal, and Tayasal, landing at Flores, capital of the Department of Petén. He remained at Chichén until August, dividing his time between administrative work and reading proof of his monograph upon the inscriptions of the Department of Petén, Guatemala.

38.34.

SYLVANUS G. MORLEY

Chichén Itzá

YB 37:141–143, 1937

The Chichén Itzá Project of the Carnegie Institution of Washington began its fifteenth year in January. Dr. and Mrs. Morley reached Yucatán by way of Mexico City on December 28, and Messrs. E. T. P. Kennedy, R. T. Patton, J. H. Denison, Jr., and W. E. Shepherd (the last two, members of the Fifth Campeche Expedition) on

January 6. Mr. Karl Ruppert, Director of the Fifth Campeche Expedition, reached Yucatán by way of Mexico City at the end of January and the expedition left Mérida for central Campeche at the end of February, returning therefrom early in April.

Dr. Morley devoted the first six months of the year to correcting proof on his coming monograph on *The Inscriptions of Petén*. The galley proof was completed and the first two volumes of page proof before he sailed for Europe on June 28 by way of Veracruz to attend the sessions of the Second International Congress of the Anthropological and Ethnological Sciences held at Copenhagen, Denmark, from August 1 to 6. In addition to representing the Institution at this congress he was also a member of the United States Government delegation thereto. He presented two papers: "A Review of 25 years' research in the Maya area of Middle America by the Carnegie Institution of Washington, 1914–38" and "The Rise and fall of the Maya Old Empire as established by the hieroglyphic inscriptions."

The most important activity under the Chichén Itzá Project during the current year, except the Fifth Campeche Expedition described elsewhere, was the survey of the ruins of Mayapán in northern central Yucatán, made by Mr. R. T. Patton, the expenses of which were defrayed partly by Mr. Patton himself, Mr. Percy Jackson, and Colonel F. Marion Barker, and partly by the Institution.

This survey was undertaken because the archaeological importance of Mayapán as indicated by the brief descriptions of Stephens, Brasseur de Bourbourg, and later visitors, including several of the Institution's staff, appeared to be far less than its political pre-eminence in the thirteenth, fourteenth, and fifteenth centuries, as established by the Spanish and native chroniclers, would have demanded. The early authorities describe the site as walled, but although Stephens saw a section of the wall, nothing was known of its extent.

The Institution's survey establishes that the wall surrounding Mayapán is 5.5 miles [8.9 km] in circuit, enclosing a rough oval about two square miles [5.2 sq km] in area. The wall is made of dry-laid, irregular blocks of limestone, not dressed, with a very slight batter on both sides. The wall varies from 9 to 12 feet [2.7–3.7 m] in thickness at the base and from 6 to 7 feet [1.8–2.1 m] in height outside. There was formerly a low parapet along the outer edge of the wall, though in most places, this has now fallen. There are several stairways on the inside leading to the top.

Nine entrances, irregularly distributed and ranging in width from 3 to 6 feet [0.9–1.8 m], give access to the walled area. This number was of considerable importance being that of the gods of the nine underworlds of Maya mythology, each one of which may have presided over one of the nine gates of the site.

The principal pyramids and mounds as well as the stelae are concentrated near the center of the walled oval area. This central section was divided into squares of 200 m on a side and surveyed, all constructions being exactly located. The principal axes of the central area were projected until they intersected the wall, and the central area tied thereto in four places. Finally, the 5.5 mile [8.9 km] circuit of the wall was surveyed by means of lines of sight just inside cut through the thick bush.

The constructions consist of pyramids, platforms, colonnades with drum columns, corbel-arched buildings, and four round towers, possibly astronomical, only one of which had been previously reported. There is little dressed masonry, surfacing for the most part having been effected by stuccoing. The architecture is far inferior to that of the other great cities of northern Yucatán, Chichén Itzá, Uxmal, and those of the Puuc and Chenes regions. It more closely resembles that of the relatively late site of Tulum on the east coast of Yucatán; the latter is also the only other walled site known in the Maya area. These several points indicate that Mayapán rose to political pre-eminence at a relatively late period in Yucatán history, probably not until the twelfth or thirteenth century.

Nineteen cenotes were found within the walled area, for all of which, except two, native Maya names were obtained.

Eleven stelae were located, nine sculptured and two dressed but plain. At the time Mayapán flourished Initial Series dating had been replaced throughout the Maya area by Period Ending dating, a method which, although not nearly so accurate as the Initial Series, served nevertheless to distinguish one katun or 20-year period from another within a period of two and a half centuries. Three Period Ending dates were deciphered by the writer on Mayapán monuments: Stela 1, Katun 10 Ahau, 1185 AD, probably 10.18.0.0.0 10 Ahau 3 Tzec; Stela 5, Katun 4 Ahau, 1244 AD, probably 11.1.0.0.0 4 Ahau 8 Mol; Stela 6, Katun 13 Ahau, 1283 AD, probably 11.3.0.0.0 13 Ahau 13 Pax.

The results of this survey indicate that although Mayapán reached a position of first importance only at the close of Maya history when architectural decadence was well under way, its size satisfactorily agrees with the political pre-eminence ascribed to it by both the native and the Spanish chroniclers.

An epigraphic discovery of importance made by Mr. Alfonso Villa R. on a trip to the highlands of Chiapas, Mexico, in connection with the Ethnological and Sociological Survey should be mentioned here. He reports for the first time a monument from Tila, to which the designation Stela C has been given. This records both as an Initial Series and as a Period Ending the date 9.13.0.0.0, 8 Ahau 8 Uo in bar and dot numerals.

Dr. Morris Steggerda of the Department of Genetics was at Chichén Itzá for the eighth season in connection with his anthropometric, ethnological, and sociological studies. His experimental milpa is now entering its fifth year, and this protracted investigation of corn cultivation as practiced by the modern Maya is proving one of the most fundamental studies made by the Institution in the Maya field.

As usual the Institution's headquarters at Chichén Itzá were again utilized by investigators of other organizations. M. André Remondet, winner of the Grand Prix de Rome in 1937, having elected Maya architecture as his field for special study, spent three months at Chichén Itzá in the winter and early spring making measured drawings, ground plans, and elevations of some of the more important buildings: the Castillo, the Mercado, the Vapor Bath, and the Temple of the Three Lintels. These drawings together with wash drawing of the last were exhibited in the French Academy at Rome, during May.

During June Dr. and Mrs. C. L. Lundell of the Herbarium of the University of Michigan were at Chichén Itzá collecting botanical specimens in connection with the former's study of the botany of the Yucatán peninsula. In July they spent three weeks collecting at Cobá in northeastern Yucatán, using the Institution's camp equipment from Chichén Itzá and taking with them as assistants several Maya from the neighboring village of Pisté, who have been working for the Institution in Yucatán during the past 15 field seasons. The month of August was devoted to collecting in the northwestern part of Yucatán near Mérida and the ecologically important northwest coast region.

38.35.

ALFRED V. KIDDER

Contract With Government of Mexico

YB 38:243-244, 1939

At the close of the field season Dr. Kidder joined Dr. Morley in Mexico City to arrange with Dr. Alfonso Caso, Director of the National Institute of Anthropology and History, and Lic. Gonzalo Vásquez Vela, Secretary of Public Education, for a 5-year renewal of the Institution's permit for research in Mexico, the former permit, which expired in 1937, having been extended for the single year 1938. This temporary extension was

requested by the Institution in order to allow time for study of the whole Division program and, in particular, for consideration of the future status of Chichén Itzá.

Since 1924 the Division's Mexican activities have centered about Chichén Itzá. The Chichén hacienda served as headquarters for the ethnological work of Dr. Redfield's group, the medical research of Dr. Shattuck, the studies in physical anthropology, agronomy, and human geography of Dr. Steggerda, and for many other workers in history, linguistics, botany, and zoology. The many exploring expeditions in Yucatán and in the country to the south were based upon and equipped from Chichén. The large scale excavations mentioned earlier in this report went forward there from 1924 to 1935. The activities fostered by Dr. Morley at Chichén Itzá were directly responsible, indeed, for the conception and the later development of the broad program of Maya research now being carried on by the Division.

In the early thirties, however, it became evident that when the excavations then under way had been brought to a conclusion, we should know as much regarding the local antiquities as was, for the time at least, necessary; and that it would be desirable to halt operations at Chichén Itzá and follow into other parts of the peninsula various promising archaeological leads which had opened up. For this reason no major digging was done at Chichén Itzá after 1933, and the next three years were devoted to study of the structures that had been cleared. The last actual excavation was done in 1936, and since that time, although the hacienda has continued as headquarters for Dr. Morley and as a base for other workers, Chichén Itzá has been of decreasing importance as a research center.

The rent and upkeep of the hacienda have been expensive and, since the opening of a motor road from Mérida, there has been an increasingly serious drain upon Dr. Morley's time and energies for the entertainment of visitors. To discuss with Dr. Morley these problems and related matters bearing upon future work in Yucatán, President Bush and the Chairman visited Chichén Itzá in February. It was then decided to give up the hacienda and establish a less costly and more central station in Mérida. At the same time there were drafted proposals for the new contract which should be requested from the Mexican Government.

In May, these proposals were laid by Dr. Morley and the Chairman before Dr. Caso and the Secretary of Public Education, and a 5-year contract was granted under which the Division is permitted to operate under most favorable conditions, but its obligated expenditure for field work is reduced from \$20,000 to \$6,000 per annum. This reduction was desired for several reasons: first, because of the general financial stringency; second, because, the results of the Chichén Itzá exca-

vations being still not fully published, no new major projects can be undertaken for several years; and, third, because the work for the immediate future is planned to consist, for the most part, of relatively inexpensive, but highly important, reconnaissance surveys.

38.36.

SYLVANUS G. MORLEY AND
GEORGE BRAINERD
Yucatán

YB 40:295-297, 1941

Dr. Morley remained in Yucatán throughout the year, engaged in completing the manuscript of his history of the Xiu family, founders of the city of Uxmal. In February he spent a fortnight at Uxmal with the following objectives: 1. The assembling of the broken and, in some cases, fragmentary stelae on the stela platform about 150 m west of the northwest corner of the Monjas Quadrangle; 2. Further excavations in the Ball Court for the purpose of locating still missing fragments of the two rings, each of which has a hieroglyphic inscription on its two sides; 3. The assembling and repair of the several hieroglyphic panels which formerly faced the three platforms in the so-called Cemetery.

The stela platform was discovered by Mr. Frans Blom, of the Middle American Research Institute of Tulane University of Louisiana, in 1932 during an expedition undertaken by that institution to obtain data for the reproduction of the North Range of the Monjas Quadrangle at Uxmal for the Century of Progress in Chicago the following year.

Sixteen stelae, all broken, were found on the platform. Their several fragments were fitted together and arranged for photographing; all, but one, were found to be sculptured. Of these, 14 are carved on the front only, and the remaining monument, of which only two pieces were recovered, is sculptured on all four faces. The stelae vary in height, including the plain butts from 1 to 5 m, and formerly stood in three or four rows across the back (north) side of the platform, all facing south. The stela platform is about 20 m square and, from 1 to 2 m high, depending on the inequalities of the terrain. Along its east-side is a lower terrace about 5 m long, though the platform would seem to have fronted south; since the stelae all faced in that direc-

tion. Thirty-eight monolithic columns or truncated cones were also found varying in height from 30 cm to 1.6 m, and three miscellaneous sculptured stones. The inscription on one of the stelae surely begins with the day 12 Ahau; if this day corresponds to a katun ending, the most plausible assumption, the two most likely Long Count positions are: 10.17.0.0.0, 12 Ahau 3 Yax (1165 AD), and 11.10.0.0.0, 12 Ahau, 3 Cumhu (1421 AD), the former being much more probable on historic grounds.

The investigation at the Ball Court was undertaken in the hope of finding additional fragments of the inscription on the rings which had been tenoned into the walls on the two sides of the court. This inscription is exceedingly important, as shown by Dr. Morley in 1918 [Chapter 1.6], since it may well record the day on which the Maya officially adopted their significant calendar change of shifting the positions of the days in their month one day forward. Excavations were carried out to a distance of 3 m on each side below the former position of each ring, and to the original floor level of the court. Three additional fragments of the east ring and five of the west ring were recovered.

Six fragments of the east ring have been found: 1. The part still tenoned into the wall; 2. A fitting section found by Dr. Morley in 1918; 3. A section found by the caretaker at Uxmal sometime between 1918 and 1923; 4. A section which fits no. 3, found by Dr. Morley during the current season; 5. and 6. Two small flakes also found by Dr. Morley this year, which fit none of the other pieces.

Six fragments of the west ring have also come to light: 1. The part still tenoned into the wall; 2. and 3. Sections found this year which not only fit together but also the section still *in situ*; 4. and 5. Sections also found during the current field season which, though fitting each other, do not fit any other sections of the west ring; 6. A small corner which fits nowhere, also found this year.

Of the epigraphic material presented by the new fragments, the most important is the repetition of the day 12 Ahau, preceded by the Winged Cauac variant of the tun sign. This decipherment is certain and tends to corroborate the probable occurrence of the same day on another section of the east ring, where it follows with a Tun 17 or a Tun 18, also represented by the Winged Cauac variant of the tun sign.

The hieroglyphic panels on the facings of the three low platforms at the Cemetery were in danger of becoming lost. Small flakes of these had been broken off by the action of milpa fires and lay scattered about. These were cemented back into place and a rough attempt was made to assemble the blocks of the three platforms in their original position. Further work should be undertaken here in order to prevent the loss of this important hieroglyphic inscription.

In addition to the foregoing work, the whole south side of the Cemetery was cleared of bush and there was exposed the original architectural scheme of this misnamed group, a court surrounded by buildings on three sides and a high pyramid and temple on the north side, the enclosure being entered by an arcade passing through the middle of the building on the south side.

Dr. George Brainerd, who was at Chichén Itzá during the past field season (1940), stayed in Yucatán during the summer, fall, and early winter, returning to the United States in February of this year. He devoted all his time to a study of the ceramic material recovered by the Institution during the 17 years of the Chichén Itzá Project.

Mr. Joseph Lindon Smith was with Dr. Morley at Chenkú near Mérida for three months. He accompanied Dr. Morley to Uxmal and made a number of oil paintings there. He also spent 10 days at Chichén Itzá working on another canvas, and the rest of the time copying sculptures in the Museum of Archaeology and History at Mérida.

Mr. Smith returned to the United States early in April, and Dr. Morley sailed from Progreso to New Orleans April 12.

38.37.

KARL RUPPERT

Investigations at Chichén Itzá

YB 45:205–206, 1946

During the Division's activity at Chichén Itzá (1925–37), numerous structures lying outside the area occupied by the principal groups were examined by Mr. Ruppert when opportunity offered. In reviewing the notes on these and on other buildings, excavated but as yet unpublished, he found it necessary to re-examine some of them and desirable to study the great number of others shown on the map of the Chichén area surveyed by the Institution in 1924, 1929, and 1932.

Mr. Ruppert left New Orleans February 5, 1946, for Mérida, Yucatán. A trip was made to the city of Campeche to examine the collections and to photograph stelae in the local museum. Sr. Raul Pavón Abreú, Director of the museum, was of much help in this activity and also made it possible for Mr. Ruppert to visit

the ruins of Edzná in his company and that of the governor of the state, Lic. Lavalle Urbina. Sr. Pavón has successfully accomplished the excavation of the principal temple at Edzná and deserves unqualified praise for the excellent organization of the Campeche Museum.

Returning to Mérida, Mr. Ruppert visited Uxmal and then proceeded to Chichén, where he remained until April 8. During his stay he was the guest of Sr. Fernando Barbachano, head of the Mayaland Tours. Sr. Barbachano's invitation was extended in furtherance of the Institution's archaeological activities, a courtesy most deeply appreciated.

Seven weeks were spent at Chichén Itzá, and over 130 structures were studied, measured, and photographed. Only minor excavations were possible in the time available and under the agreement with the Mexican government.

There does not seem to have been an organized plan or arrangement of structures for the area as a whole. Buildings face in all directions, the most common being west; seldom does one face south. Connecting some of the groups are ancient ceremonial roadways or *sacbé*s. One, Sacbé no. 7, extends from the Monjas to the Temple of the Four Lintels, tying together the northern and southern parts of the city. On either side of this roadway, but not directly connected with it, are small assemblages of structures. Throughout the area are isolated terraces and platforms supporting buildings that appear to have been independent units.

Platforms vary greatly in size and shape and have from one to four stairways. Some do not support buildings, others support one or more. The former are classed as shrines or dance platforms and are often located in front of a temple-type structure. When a platform supports a single building it rarely has more than one stairway.

Pyramidal substructures are always covered with debris fallen from above. Infrequently is any of the facing exposed.

Occasionally, part of the base of the stairway may still be made out, and seldom is there more than one stairway; the Castillo and the High Priest's Grave are exceptions. Superstructures are found in varying states of ruin. Some are now little more than rubble heaps which give no clue to their former nature.

Colonnades have a general distribution. No new ballcourts were encountered. The six courts in the area are confined to a rather small section around the principal groups.

Hitherto, serpent columns have been found associated with only eight buildings. A ninth was added this season. It is a small two-chambered structure (3E-5) apparently resting directly on the great northern

platform that supports the Castillo, Temple of the Warriors, and other buildings. One of the columns was partly excavated. The serpent head was not found. It was not an integral part of the first drum as, with one other exception, is the case when the column is round. The upward projection of the tail, not recovered, was a separate stone.

Five additional structures of the gallery patio complex type, best represented by the Mercado but not noted in the report on that building (Ruppert 1943:224), were recognized this season. One may not have had a gallery, three have shrine rooms, one has no columns in the patio, and one has a patio with vaulted chambers on two sides. This latter feature is of considerable importance, and it is regretted that the structure was in such collapse that it was impossible to obtain an accurate ground plan. Vault stones were not noted in the gallery of two of the structures. This is a highly specialized type of building, which, however, shows considerable variation in the 11 examples now known at Chichén Itzá.

Mr. Ruppert flew to Mexico City April 10. A trip was made to the ruins of Tula in the state of Hidalgo. This site has a number of affinities to Chichén Itzá. Of special interest is a structure somewhat similar to those of the gallery-patio complex type. April 25 was spent at Tajín, Veracruz. Owing to an early rainy season, excavations by the Mexican government had been suspended. Mr. Ruppert returned to the United States May 5.

38.38.

KARL RUPPERT, EDWIN M. SHOOK,
A. LEDYARD SMITH, AND

ROBERT E. SMITH

*Chichén Itzá, Dzibiac, and Balam Canche,
Yucatán*

YB 53:286–28, 1954

Ruppert and A. L. Smith spent 11 days at the ruins of Chichén Itzá for the purpose of exploring the site for house types. They found the task difficult because of the thickness of the vegetation and the poor condition of the structures. A large part of the mapped area was covered, as well as some terrain slightly off the map,

and 43 houses were found in good enough condition to yield plans. These were found on low, flat ground and on large platforms, many of which border the *sacbé*s, in Squares 5B, 6B, 7B, 3C, 4C, 5C, 4D, 5D, and 4E, and off the map east of 4E. During this search for house types two unreported *mercado*-type structures were discovered.

The house types, although in some cases slightly different, are closely similar to those found at the Puuc sites of Uxmal, Kabah, and Sayil, and are unlike those at Mayapán. Of the 43 houses investigated were tested for pottery. Four had Toltec-Chichén Period pottery above floor including large effigy censers similar to those found at Mayapán, numerous Slipped Red Ware jar sherds, many from one vessel which were not the same as Mayapán Red, and a few Black on Cream sherds. The rest of the pottery from house types, including some from below floors, belonged to Toltec-Chichén Period. This suggests a late re-use of certain houses.

Shook and R. E. Smith made a ceramic survey of Chichén Itzá from March 14 to April 8, during which time a day was devoted to excavations at each of two nearby sites, Dzibiac and Balam Canche. Our objective in making a study of Chichén Itzá pottery was to check the range of the site's occupation in the light of established ceramic chronology at Mayapán. In particular, we hoped to encounter refuse deposits of long duration or in association with the well known Maya and Toltec styles of architecture in Chichén Itzá. Another objective we believed to be of prime importance for Yucatán and Mesoamerican prehistory was a knowledge of the full range and context of ceramics pertaining to the epoch of Toltec influence in Chichén Itzá.

We began the study by making a surface reconnaissance covering the major portion of the area shown on the map of Chichén Itzá. It was observed that the map shows the larger structures of the site but fails to include the majority of the lesser mounds. In some groups the latter outnumber the more impressive buildings. Many of the unmapped mounds are ancient houses. They often occur on the same terrace in close association with the larger and frequently vaulted, structures; others may be on extensive stone-filled platforms with no large accompanying units. The map shows the platforms, though rarely the low mounds upon them. Large sections of terrain were almost barren of surface pottery or other indications of a concentrated population in ancient times. These conditions prevailed especially in the south-central and southeastern sectors, and in the area lying north and northeast of the great terrace or platform supporting the Castillo, Great Ball Court, Court of the Thousand Columns, and other structures. The preliminary re-

connaissance served to identify these zones as unfavorable for the location of deep refuse deposits and to suggest that the best opportunities lay in the immediate vicinity of terraces or platforms on which large vaulted buildings were concentrated. Invariably, the deepest middens were found off the edges of these terraces. The contents of the middens, discussed below, we believe suggests that they were an accumulation in part of household refuse, in part of ceremonial material. That many people lived in close proximity to the large civic and religious buildings seems certain from the evidence.

We made 19 ceramic cuts at Chichén Itzá. The locations of these include the principal groups of the site from its southwest to its northern limits. The procedure, after finding by surface observation a location which appeared favorable for pottery dumps, was to dig a test pit or trench from the surface to bedrock, removing arbitrary levels of 25 cm unless floors or other divisions were encountered. Some of the tests proved unproductive; others cut through stratified refuse. In the latter instance we often enlarged the area excavated to obtain an adequate sample of material.

The pottery from only nine cuts has thus far been recorded and subjected to preliminary analysis. The results are most instructive, in spite of the fact that four of these cuts were ceramically unproductive, lacking stratigraphy and sufficient sherds to do more than date the platform or construction penetrated. Cut 2 was a good example of a productive cut. There were three strata and a floor sealing off the two lower levels. The latter contained nothing later than Puuc types, whereas the above-floor level yielded mostly Toltec-Chichén types and a few Puuc specimens. Cut 8, with three arbitrary strata, showed a slight change from bottom to top, but all the pottery was within the Toltec-Chichén Period. This same ceramic pattern was found in the four strata of Cut 14, where Fine Orange X formed less than one percent in the two upper strata as compared with 5.3 and 4.9 percent, respectively, in Strata 4 and 5 of Cut 17, unquestionably the most important cut for establishing Toltec-Chichén ceramic types. These types were present in all six strata of this deep midden. Puuc specimens associated with the three lowest levels were lacking in the upper levels; Chichén Medium Slate Ware became more abundant as the surface was approached. Cut 13 was the only one which appeared to harbor post-Toltec-Chichén ceramic types, including unslipped lightly striated jars and Black on Cream vessels similar to those found in the lower levels of the principal period of occupation at Mayapán. These types occurred both below (21 percent) and above (48 percent) a well preserved floor. The only other types recognized in this cut were of the Toltec-Chichén Period.

The principal ceramic types of the Toltec-Chichén Period as found in Cut 17 comprised: unslipped jars often with pattern-striated bodies and bolster rims; censers, hourglass type sometimes embellished with buttons or spikes set in a painted blue background, jar-shaped with three hollow bulbous feet, or ladle type, a few of which may have been painted red with a blue lip border; Chichén Medium Slate vessels (jars, bowls, usually without feet save for grater type; restricted-orifice bowls with bolster rim, and rarely bolster-rim basins), which had a light translucent cream slip showing the brick-red paste underneath; Chichén Red vessels (jars, round-sided bowls with flat or impressed disk base and occasionally with black design; flaring-sided bowls with everted rim and sometimes gouged and incised through a cream band; and rarely cylindrical vases), which were somewhat mottled but otherwise smooth and waxy to the touch and quite like the Puuc Red types; Fine Orange X, and a polychrome Fine-Orange like that from Isla de Sacrificios, Veracruz; hard yellow ware with black trickle (jars, restricted-orifice bowls with bolster rim, and flaring-sided bowls); and a very few Tohil Plumbate vessels.

The primary facts gleaned from our work are: 1. There is no pottery at this site earlier than the Puuc Period, save for a collection of Formative types from a single cut east of Structure 3C-6; 2. There is no pottery later than the Toltec-Chichén Period but for a small quantity of Black on Cream (Brainerd's coarse slate) sherds from Cut 13, a pit just south of the Mercado; 3. The content of the Toltec-Chichén ceramic phase is established by means of Strata 4 and 5 of Cut 17, where the greatest concentration of Fine Orange X was found.

The reason for finding almost no material later than the Toltec-Chichén Period in the 19 cuts is presumably that the permanent occupation of Chichén Itzá terminated at or near the end of that period. The few Black on Cream Ware sherds, usually thought to belong to a later period, may have been precursors of, and thus slightly earlier than, the similar, early Mayapán Period type. The explanation for the late sherds found above the floors of certain house-type constructions is probably that people were re-using the houses in late times. These people may have been pilgrims who each year occupied the better preserved houses during their visits, leaving behind some broken utilitarian pottery as well as censers. That people returned to an abandoned and ruined Chichén Itzá to worship is made clear by E. H. Morris (1931:179–180) in describing the pottery, mostly of the large effigy-censer variety but including some red ware tripod plates found “in vegetable mold just beneath the surface, most plentiful in front of the doorways and strewn down the stairs.” He also describes pottery,

found on the floors of buildings, which closely resembles what has been listed above under Toltec-Chichén types. These wares were “in use while the buildings were still standing.” The findings resulting from the 19 cuts made by Shook and Smith entirely agree with conditions described by Morris.

The ruins of Dzibiac were visited briefly. They are situated about 10 km west of Chichén Itzá, around a beautiful cenote bearing the same name. We noted several platforms with fallen structures on them and two buildings with standing or partly standing vaulted rooms. The larger of the two lies about 50 m southwest, the small some 200 m north, of the cenote. Each has remains of vaulted chambers around two or more sides of a thick masonry core, resembling in this respect many of the palace-type structures of the Puuc region. At Dzibiac the masonry of the room walls consists of roughly cut blocks laid in regular courses with a considerable number of spalls between stones. The undressed blocks are well tenoned into the hearting in contrast to the shallowly tenoned veneer stones of Puuc and Toltec-Chichén architecture.

The vault masonry is strikingly different from that used in the walls. The vault stones have semi-specialized, long tenons and are excellently cut and dressed on the exposed faces. They are laid evenly, producing a rather true plane from the offset at the vault spring to another offset just under the capstone. The structure nearest the cenote has a series of small subterranean vaulted chambers honeycombing the central block of masonry. Their size and position suggest that they served as burial chambers, but the local people have a more colorful interpretation. They believe the tiny vaults were the home of elves, the little people, and refer to the ruins by the name *alux*, or dwarf.

We observed no carved stone elements of architectural ornamentation or doorway columns at Dzibiac. The masonry and style of architecture conform most closely to the pre-Toltec buildings in nearby Chichén Itzá. The pottery from a trench dug off the west terrace of the building with the burial chambers belongs to the Puuc, or Late Classic, Period.

Shook made a preliminary exploration of the site and cave of Balam Canche, and later returned with R. E. Smith for a more thorough investigation. The ruins surrounding the mouth of the cave have not been reported previously, although the cave has long been known. The site lies 4–5 km east of Chichén Itzá and is readily accessible from the recently paved Mérida Valladolid highway. The ruins, only 300 m north of the highway at Kilometer 124.5, served as a stone quarry during the road building operations. Much of the site was destroyed by this work. Left were remnants of a masonry wall enclosing the cave entrance, a mound, and two vaulted buildings and several low

house foundations on what originally had been an extensive platform. The last enclosed the eastern half of a plaza in the center of which is located the cave entrance. The vaulted structures had walls of roughly cut, undressed blocks; doorway jambs of carefully cut and dressed, full-width stones; plain stone lintels; and semi-specialized, well cut and dressed vault stones. None of the building stone observed bore carving. Architecturally, the two vaulted structures in Balam Canche are similar to those at Dzibiac. A surface collection of pottery and material from a ceramic trench through the platform east of the cave indicate a long period of occupation. The building activities, however, took place during the Puuc or Late Classic Period.

The natural cave with its several water sources has been investigated by A. S. Pearse (1938) and others principally interested in the fauna of Yucatán caves. From time to time selected samples of pottery were collected from the cave floor. These sherds, studied by Vaillant, Roberts, and Brainerd, led to the establishment of a ceramic type which Brainerd calls Incised or Flaky Dichrome and places stylistically in the begin-

ning stage of the Early Classic Period. We made three excavations in the cave floor by the water pools nearest the entrance and collected a large sample of pottery from the surface of the floor throughout the cave. A small stone sculpture depicting a human figure in kneeling position also came from here.

The pottery within the cave, like that recovered from the ruins, showed a long range of occupation. Most abundant on the surface of the cave floor was Puuc Medium Paste Slate Ware of the Late Classic Period, and there were a few sherds of the Toltec-Chichén, Mayapán, and Postconquest Periods. In two excavations, only Preclassic and Early Classic types were found. The oldest material consisted principally of lustrously polished, red-slipped jars. These do not bear handles of any kind, nor do the Incised Dichrome jars which directly overlie the Preclassic Red and Orange monochromes. Several sherds cannot be distinguished macroscopically from the Pattern Burnished Ware which Brainerd discovered in the Maní cenote and considers to be the most ancient pottery so far recognized in Yucatán.

39.0. EK BALAM

The core of the site extends over an area of approximately 6 sq km, and is surrounded by two walls. Structure 1 is 150 m long, and the largest construction at the site. Recent excavations by Tulane University have revealed a well-preserved stucco façade and a flight of steps inscribed with hieroglyphs. Most buildings date from the Late Classic period, although other finds at Ek Balam suggests a Preclassic occupation. Désiré Charnay visited the ruins at Ek Balam in 1886 on his last trip to Yucatán. Sylvanus Morley and Jean Charlot visited Ek Balam in the late 1920s and published a brief description of the site, which they believed to be late Postclassic. In the early 1980 Ian Graham examined the carved monuments at the site and, beginning in 1985, William M. Ringle and George J. Bey spent several seasons at Ek Balam. Work included mapping of the site core, and peripheral sites. Ceramic collections were taken and analyzed and some of the standing architecture was cleared.

39.1.

SYLVANUS G. MORLEY

Report on the Ek Balam Expedition

YB 27:317–318, 1928

On June 4, Dr. Morley and Mr. Charlot left Chichén Itzá for Valladolid, and thence north 15 miles [24.1 km] to the ruins of Ek Balam. This site had been previously visited and described by the French explorer, [Désiré] Charnay (1886), but a recent report of a hieroglyphic inscription there initiated the advisability of further exploration.

Ek Balam must have been a center of some importance from the size and extent of the remains, although comparatively late. The buildings are low and built of crudely dressed masonry. Carved or even cut stones are almost entirely wanting, and the walls seem to have been finished, for the most part, with stucco as at Tulúm. The very low height of the corbelled arch, in the single intact chamber seen, strongly recalls the similar low arched chambers of buildings along the East Coast, which are certainly of late origin, having been occupied down to the time of the Spanish Conquest. On architectural and stylistic grounds, it is more than probable that Ek Balam was a contemporary of Tulúm and the other East Coast sites, and that it too

was occupied until the early part of the sixteenth century.

One of the highest pyramids had a human figure made of stone and stucco on one side of a doorway leading to a chamber near the top. This was a very grotesque, crudely executed and without esthetic merit.

A large altar 7 feet [2.1 m] long, 7 feet [2.1 m] wide and 7 feet [2.1 m] high, carved from a single block of stone, was found standing by the out-cropping of the native limestone from which it had been quarried. Its entire top had been hollowed out to the depth of 5 or 6 inches [12.7–15.2 cm], leaving a rim 4 inches [10.2 cm] in thickness. The front is carved with a grotesque hu-

man face having large circles around its eyes, suggesting the Tlaloc head; the back and sides are plain, though dressed.

A single carved stela was found in a similar position, that is, lying on the ground by a similar out-cropping of the limestone. This had a rounded top and a small simplified serpent with a plumed head-dress on the front. There were no glyphs on this monument and the back and sides are plain, though dressed.

Ekbalam was obviously a late provincial center, and its architecture and sculpture are such as might be expected in a Maya site of this late degenerate period in the northeastern corner of Yucatán.

40.0. MAYAPÁN

Between 1951 and 1955 the CIW conducted extensive excavations at Mayapán. The site was selected for intensive research and excavation to study the late prehistoric Maya in Yucatán as described in the native literature. According to the historical narratives, Mayapán was the political capital of the Maya in the Yucatán peninsula from about the late 1220s until the 1440s. In 1221 the Maya revolted against the Maya-Toltec lords at Chichén Itzá. After a short civil war the lords of various cities restored a central government to Yucatán, and constructed a primate settlement near the town of Telchaquillo. The chief of the Cocom, an ancient lineage that had taken part in the revolt against Chichén Itzá, was selected as king, and other noble lineages and regional lords were invited to provide people to serve in the government at Mayapán. This arrangement lasted for over 200 years. In 1441 Ah Xupan of the powerful Xiu lineage organized an insurrection against the Cocom rulers. At the end of this most of the Cocom family were killed, Mayapán was sacked, burned, and abandoned, and Yucatán fell apart into warring city states. It was thought that field archaeology might help in the solving of problems and contradic-

tions created by the literature. Another reason was to investigate the relation of the late historical disturbances to the military and cultural aggression from the Mexican highlands. The CIW project at Mayapán included their most ambitious settlement mapping effort. A. L. Smith characterizes the site as a Late Postclassic period (ca. 1260—1460 AD) urban concentration of 4,000 structures, including 2,100 dwelling units. The whole is encircled by a defensive wall which embraces 4.2 sq km. A group of temples and palaces lie in the center of the enclosure, and the dwelling units are scattered at random throughout the periphery. Mayapán is estimated to have housed some 11,000 to 15,000 people.

40.1.

MORRIS R. JONES

Survey and Base Map at Mayapán

YB 49:194–197, 1950

In accordance with arrangements made by the Institution and the U. S. Geological Survey, Mr. Morris R. Jones reported to Washington, November 1, 1949, where papers, instruments, and instructions necessary for his entrance into Yucatán and his work in the ruins of Mayapán were procured. Proceeding by way of New Orleans, Jones was met in Mérida November 4 by Mr. Shook and Mr. Strömsvik of the staff of the Division. Over the ensuing week and a half Shook and Strömsvik assisted Jones in acquiring supplies and equipment, hiring native labor, and coming acquainted with the ruins.

It was decided that Telchaquillo, a small village 2 km north of Mayapán, would be the best base of operations, and quarters there were occupied November 10. Telchaquillo is accessible from Mérida by road, and throughout the season it did in fact prove to be a good location, mainly because of its proximity to the ruins and the fact the native labor supply in the village was both adequate and of good quality, the natives being interested in, and sympathetic with the project as work progressed.

Reconnaissance and survey at Mayapán during the 1938 season by Mr. R. T. Patton [Chapter 1.27] proved valuable in planning this season's operations. Several facts were known, about the site. The ancient city is surrounded by a wall, roughly oval, extending approximately 3,200 m east-west 2,000 m north-south, the area outlined being 4.2 sq km. Ancient gateways are to be found at intervals along the wall. A large pyramid, similar to the Castillo at Chichén Itzá but smaller, many closely spaced colonnades, small pyramids, and three round towers form a main group a little west of the center of the walled area. Another, rather small ceremonial center is just inside the eastern limit of the area.

The wall presented a distinct advantage in the making of the map because it forms a definite boundary, and during the course of the work exploration and mapping were limited to about 75 m outside the wall. Ruins were found within this outer fringe, and it is known that more are beyond it, but they are sparse and hardly worth the effort of mapping when so much lies within the primary area.

A scale of 1:2,500 had been decided on; the contour interval selected, was one meter. As there is no vertical control in the immediate area, an elevation of 25 m above

sea level was assumed for point 0, so that all elevations and contours are based on this datum. It may be possible at a later date to connect the datum with a closed vertical control line of the Mexican Government.

Actual work was begun November 12 with the selection of a point of origin as close to the center of the city as could be determined from information available. This point, a triangle cut in bedrock, is located along the trail which connects Rancho San Joaquín with the main road running south out of Telchaquillo. It is 31 m northeast along the trail from the gateway into the ranch. In beginning the survey, point 0 was occupied with transit and Polaris observations taken at night in order to determine true north. As an azimuth mark, a cross was cut in the top of the southernmost pillar of the gateway into Rancho San Joaquín. The south azimuth from point 0 to the mark was computed to be 28 degrees 54' 24", and the approximate magnetic declination for the area is 6 degrees 30' east.

With the true cardinal directions determined, a plane-grid system was laid out over the area, the net, when completed, giving squares 500 m on a side with 100 m stations established along all lines. Each 500 m station was marked by a triangle chiseled in bedrock where possible or by a large hub where the point fell on soil. Hundred-meter stations were marked with hubs surrounded by piles of stone.

All lines had to be cut, of course, and, four men were kept ahead of the instrument party clearing a path through the dense growth. Native workmen were trained to plumb chain and to set stations exactly on line, work which they learned quickly and performed accurately. Grid lines were carried until the wall was encountered, where they were discontinued after explorations just beyond. While this work was being done, two men were employed cleaning brush from the wall to provide easier passage when the time came to do plane-table mapping along it. Establishment of the plane-grid network, which includes about 20 km of line, was completed December 31, the density of the bush slowing the rate of progress.

A system of numbering stations was established, and the squares formed by the projection lines were given letters. It was thought that these 500 m squares would provide convenient units for separate archaeological investigation should such prove desirable, and an attempt was made to locate the grid lines so as to include the Main Group within one square. The cutting of these lines afforded a clue to the density of remains within the wall, and the first part of the survey showed that there are many more ruins at Mayapán than had hitherto been supposed.

Plane-table topography and culture were mapped by working first along already cleared projection lines.

An area of approximately 50 m on either side of the line was included. After a square had been surrounded, the interior was mapped by cutting four lines southward from the four 100 m stations along the north edge of the square. By covering the area 50 m on either side of each interior line, the square was completely explored. Each square was treated similarly. Approximately 65 percent of the city was mapped this season, including the Main Group and the small ceremonial group to the east.

As the season's operations drew to an end, a transit station was established atop the main pyramid in order to triangulate on three known positions which are part of a third-order closed triangulation net of the Mexican Government. The geodetic co-ordinates of the main pyramid were determined by this method to be latitude 20 degrees 37' 47.88" N, longitude 89 degrees 27' 41.40" West.

Two facts concerning Mayapán serve to verify old records which describe it as a populous city. In the first place, the density of remains found within the wall is high. A rough estimate would set the number at 3,500 individual ruins, which still can be detected, plus many terraces, all within an area of about 1.6 square miles [4.1 sq km]. Many more, of course, have been erased by the constant stone-robbing that has gone on since the beginning of the Spanish occupation. Rancho San Joaquin, within the walled area, and Hacienda Xanchakan, 4 km to the west, were constructed wholly or partially of stone from the ruins.

The other fact testifying to the former population density of Mayapán is the number of cenotes found within the wall. During this season seven cenotes were noted: four leave the water table exposed, and three give evidence that water was once obtained from them. It is known from Patton's survey that more cenotes will be encountered as the map is completed. Several others are known within a 5 km radius of Mayapán; for example the one at Telchaquillo, from which water is still taken and around which ruins are to be found.

Only a small percentage of the remains, those in the Main Group for the most part, appear to have been ceremonial structures or the like. Most of the ruins are small, averaging 10 by 5 m, and having a typical floor plan. It seems logical to assume that these small ruins were dwellings. More often than not, two or three are so situated as to form an obvious unit, the remains being close together and on the same terrace. Metates are consistently to be found on the smaller, or smallest, ruin of the group, and in many cases an altar is a definite part of the unit. It was noted that some of these units are made up of ruins slightly larger, better terraced, and in more choice topographical locations than the average. In a few cases drum columns supplement what seems to have been the standard floor plan.

Some 300 m east of the main pyramid are located three relatively large and interesting building units, each quadrangular, two having vaulted passages connecting their inner courts with the outside. These structures appear to be of the so-called palace type. A *sacbé*, or paved way, connects the westernmost "palace" with another relatively large ruin 300 m to the southwest.

In summary, the remains found at Mayapán are numerous but the architecture appears to be far inferior to that of the other great cities of northern Yucatán. As has been mentioned, the individual ruins are in an extreme state of disrepair.

At the end of field work a week was spent in Mérida to complete office work on the map sheets. Mr. Jones left Yucatán June 17 and reached Washington June 19, 1950.

Although thanks are due to many persons who assisted in this work, they should be extended particularly to the U. S. Geological Survey for its fine cooperation and the numerous facilities it has provided.

40.2.

MORRIS R. JONES

Survey and Base Map at Mayapán, Yucatán

YB 50:229-230, 1951

In accordance with arrangements made by the Institution and the U. S. Geological Survey, Jones returned to Yucatán on November 2, 1950, and, after reoccupying quarters at Telchaquillo, resumed work on November 6. He was able to engage the same group of native workers who had served him the year before, so that no time was lost in readjustment.

During the previous season, a grid network was surveyed over the ruin area and lines were cut through the dense underbrush over this grid. Topography and culture were mapped by plane table methods, as described [Chapter 40.1]. At the beginning of the second season, the still unmapped portion, approximately 35 percent of the entire area, included the city's eastern and, southern limits. It should be remembered that the ancient wall which forms the map boundary is irregularly oval in shape.

The density of ruins in the eastern area was found to be low. Of note, however, is an interesting group close to Cenote Itzmal Chen. It includes four structures

so situated as to form a quadrangle, all built on the same terrace, and with a small round building at the quadrangle's center. The northern structure of this group is the tallest and most massive. An ancient gateway was found at the wall's northeastern-most point, another where the wall passes near Itzmal Chen, and a third at the wall's southeastern extreme.

Work in the southern part of Mayapán proved fruitful because house mounds were found to be numerous. Ruins are especially dense along the wall's southwestern extreme, and cenotes are numerous in that area. Of particular note was a house group on which two carved stone plaques were found. At this same group is a monolithic altar about 1 m in height. Another house construction could be seen to have been built over an earlier, and subsequently filled, vaulted room. Along the wall's southern arc are one major gateway and two minor passageways.

The wall's entire perimeter reveals six main ancient gateways and four minor ancient passages. The wall has been broken through at several places for the passage of modern trails, and it is difficult to determine whether or not these modern breaches were minor ancient passages which have merely been widened. It is believed, however, that fresh breaks were made for most of the post-occupation trails, since one such trail passes through an ancient gateway and the original dimensions of this opening are still more or less clearly defined. Present-day inhabitants of the Mayapán area know of no names for the ancient gateways.

An over-all count of cenotes within the walled area and 100 m outside it reveals 15 which are known to have water in them today. Seven more cenote-like caverns were found to be dry, though sherds found close to some of them indicate they once were sources of water.

At the beginning of, mapping operations, an elevation of 25 m above sea level was assumed for the survey's centrally located point of origin, and all contours and map elevations are relative to this. In order to determine the error between the assumed elevation and the true position of the point of origin, a line of levels was run from known elevation at Hacienda Xcanchakan to the ruin area. Elevations as shown on the Mayapán map were found to be about 8 m higher than their true vertical position. This, error is of little consequence since all elevations on the map are relative to one another.

Mapping operations were completed early in February, and Jones left Yucatán, on the eighth of that month, proceeding Washington, where all materials were turned over to the Institution.

40.3.

KARL RUPPERT AND
A. LEDYARD SMITH
Mayapán, Yucatán

YB 50:230–232, 1951

The 1951 field season at Mayapán, Yucatán, under the supervision of Ruppert and A. L. Smith began March 3 and continued through May 17. Headquarters were established in Telchaquillo, 2 km north of ruins.

Previous work carried on at the site by Carnegie Institution includes Patton's map of the wall made in 1938 [Chapter 1.27] and Brainerd's and Andrews' reports on ceramics and architecture in 1942 [Chapter 36.3]. The excellent map of Mayapán by Morris R. Jones, completed in February 1951, served as a key to, and was of invaluable aid in, the past season's work.

Owing to the great number of structures at Mayapán, some 3,600, it seemed advisable to undertake no excavations during the first field season, but to limit the work to surface examination of as many structures as possible. At the same time likely places for future excavation were to be noted. The map had been divided by Jones into 500 m squares, each designated by a letter. To facilitate identification of individual structures, they were given the letter of the square in which they occur, plus a number. When in groups, the structures carry the same number but are differentiated by the addition of a lowercase letter. The data for each structure, in most cases including scale drawings, were recorded on a 5 by 8 inch card. Approximately one-third of the site, Squares A-E and J-N, with a total of 1,143 structures, was examined and recorded.

The area investigated is mostly limestone outcrop with little soil, supporting low, scrubby growth. The contour of the land is very irregular but does not vary more than a few meters except where it is broken by low hillocks. These latter, by far the most desirable locations, were often leveled on top and built up to support a group of buildings. Groups in general, whether on a hillock or not, are formed by two or three structures on a single terrace.

The structures examined fall into several categories: simple low platforms, dwelling-type structures, other buildings, altars, pyramidal structures, causeways, and walls.

The simple low platforms vary in size from 3 m by 5 m to 6 m by 10 m, and average 30 cm in height. They are faced with roughly worked stones.

Dwelling-type structures, usually supported by low platforms, vary greatly in details such as arrange-

ment and number of benches, walls, and passageways. These variations are undoubtedly due to the size and circumstances of the family and the personal whim of the builder. There is a great deal of evidence that original structures were added to, possibly because of increases in the family. In spite of the numerous variations, this type of structure usually consists of one room with one or more benches, or a front and back room. In the latter case the front room has at least one bench, more commonly two with a passageway between leading into the back room; occasionally three benches occur with passageways between them. Back rooms are consistently narrower than front rooms. There is little indication that the fronts of the houses were closed. The back room often had a doorway at one end. Small altars are occasionally found in the inner room, built against the center of the back wall. In general they consist of low platforms outlined with stones. Lack of any debris on the floor or benches suggests that these structures carried thatch roofs. The walls are of one course in height and never rise above 60 cm. As there is no evidence remaining to indicate that the walls rose higher, the upper part must have been constructed of perishable materials. The masonry is of roughly worked stone. Jamb stones, often better worked, may rise above the wall. Plaster, although no doubt extensively used, was found only in rare instances. Unfortunately the land has for many years been burned over for milpas, and this has caused much destruction. In general these dwellings follow closely Landa's description of house construction in Yucatán (Tozzer 1941:85–87).

The third category includes a type of structure that may also have been used for dwelling purposes, probably by the wealthier or more important residents of Mayapán. It is similar in plan to the structures described above, but is built of nicely cut and coursed masonry. These structures may have two or four columns formed of a number of stone drums, or masonry piers, across the front. Because of the amount of debris it is impossible to tell the number of benches in the front or back rooms without excavation. A very few structures of this type have been found to date.

Altars occur most frequently in front of the larger structures, especially when the latter form part of a group. They are small, rectangular masonry platforms rising an average of 20 cm. In some instances they support a low wall or a single upright stone.

A truncated pyramid rising 4 m on the south side was found in Square E. It is the only structure of this type encountered in the area investigated. Although in ruin and covered with debris, stairways flanked by balustrades were visible projecting from three sides. Two terraces high, the pyramid supports the remains of a superstructure.

A causeway with one end north of the pyramidal structure extends approximately, 100 m northwest. Averaging 2 m in width and barely rising above the ground level, it is bordered in most places by stones varying greatly in size.

An interesting feature is the frequent occurrence of alignments of stones or walls surrounding individual structures or groups. These walls, made of large stones set on end and placed a few centimeters apart, probably delimited land ownership. In some cases lanes are formed by the parallel walls of neighboring properties.

The portion of the main city wall examined was for the most part in a very poor state of preservation. Made of large rough stones, it does not rise over 2 m at any point. In some places there remain traces of a banquette and parapet. There is a gateway through the wall in Square B and another in Square D.

Structures outside the wall are infrequent. Those examined do not vary in plan and construction from those within the city proper.

An earlier period at Mayapán is suggested by the frequent occurrence of used stones. Some of these stones are carved elements of Puuc period decoration, others are nicely dressed wall stones which have been incorporated in masonry of a far inferior quality. Metates of the grooved type were found in great quantities and were often put to secondary use in masonry construction.

During the season's work it became evident that in order to have a clear picture of certain types of structure, some excavation would be necessary. With this in mind various buildings were recorded as being the most likely, to give the desired information. At the same time places that looked as if they might contain caches or burials were noted. These are in benches and built-up terraces where depressions, probably caused by a collapsed vault or crypt, were observed. In one instance the capstones and upper part of a vault were showing below the top of a bench, and it is hoped that other examples of superposition will become apparent as the work progresses.

40.4.

EDWIN M. SHOOK AND
TATIANA PROSKOURIAKOFF
Yucatán

YB 50:236–240, 1951

Shook arrived in Mérida from Guatemala on February 6, 1951, and returned to Guatemala May 31. Most of his time in Yucatán was devoted to the organization of the Mérida office as a base of operations with a ceramics laboratory and storage facilities for archaeological material. In this task R. H. Thompson and Mrs. Thompson co-operated throughout the season, as did Proskouriakoff during the two months of her stay in Yucatán.

A great mass of archaeological material, packed in about 500 wooden boxes, had been in storage for a number of years at Hacienda Chenkú on the outskirts of Mérida. This material consisted principally of pottery fragments recovered from the excavations by Carnegie Institution throughout the peninsula of Yucatán. Also, there were artifacts of stone, shell, bone, and pottery, human skeletal material, and miscellaneous stone sculpture. It had previously been arranged with the National Institute of Anthropology and History that all suitable specimens should be delivered to the museum in Mérida during the past season. It was also planned that the large collection of fragmentary ceramic material be divided into representative study lots for future deposition in various museums in Mexico, Central America, and the United States. With these objectives in mind, the entire collection was moved from storage to the new Mérida quarters, while still in boxes segregated by site, structure, or trench within a site, and when possible by stratigraphic level. The contents of each box or container then were culled, cleaned, and placed in specially designed shallow trays. Sherds too small or weathered for determination of ware, shape, or decoration, and those the provenience of which was uncertain, were discarded, as were many larger body and rim sherds of wares and forms abundantly resented in the collection. By the season's end the ceramic material had been arranged in cases, readily accessible for study, comparison, and division into type collections.

The artifacts, sculpture, and all whole or restorable pottery vessels were catalogued, drawn, or photographed, and delivered in May 1951 to the Mérida Museum. Human skeletal material was carefully packed, labeled as to provenience and turned over to the local office of the National Institute of Anthropol-

ogy and History for shipment to the National Museum in Mexico City.

As time permitted, brief visits were made to a number of archaeological sites that provide comparative and background material for the Department's studies in Yucatán. Museum as well as private collections were photographed and recorded. R. H. Thompson and Shook obtained pottery samples from the few remnants of the ancient site of Tihoo, over which the modern city of Mérida is built. Demolition of the great Maya structure, which the Spaniards used partly as a foundation and partly as a quarry in constructing a Franciscan monastery, has accelerated during recent years to provide space for Mérida's market area. From the rubble of the monastery and Maya structure was salvaged modern, Spanish colonial, and preconquest pottery. The last consisted principally of Late Classic period slate wares typical of material from Puuc sites, and a few sherds assignable to the period of Toltec influence in Chichén Itzá. The debris also contained several well cut and dressed stone disks apparently from architectural columns. This type of column was used most frequently during the Early Postclassic or Toltec period in Yucatán. No evidence of occupation after this period until Spanish colonial times was noted.

Thompson and Shook visited ruins at Candel, Ucu, and Hunucmá along the Mérida-Sisal highway, and located or obtained information of others west and northwest of Mérida. Those visited have suffered damage to a greater or less degree because they were a convenient source of stone for constructing churches, houses, or fences in the respective towns, or for the highway. Surface sherd lots were collected at Candel, at Ucu, from a low mound being cut away in Hunucmá, and from a site which had been destroyed on the south edge of the highway about 1 km east of Hunucmá.

Southeast of Mérida, Thompson and Shook investigated three sites, San Antonio, Tehuizt, and Tepich. The first proved to be a small site dating from the Late Classic or the Toltec Chichén Itzá period. Among the debris of vaulted buildings were well cut and dressed wall and vault stones and round, full-height doorway columns. San Antonio is located 1 km northwest of Hacienda San Antonio Tehuizt on the north edge of the Mérida-Acanceh highway. Southeast of the same hacienda are the ruins of Tehuizt, a major archaeological site extending at least 1 km north-south, mostly between the highway and railroad line from Mérida to Acanceh. The site is dominated by a huge, steep pyramid approximately 18 m in height. Several closed, rectangular court groups lie on the flat and barren limestone plain north and northwest of the pyramid. Common at Tehuizt are terraces retained by large rough limestone boulders, house platforms, and apparently vaulted, multiple-room, palace-type structures on low

platforms. The latter had moderately well cut lintels and full-width doorway jambs, but nowhere at the site were noted cut and dressed wall or vault stones. Wall masonry is of large rough blocks laid in irregular courses with much spalling.

Tehuitz and Tepich, a somewhat smaller site on the southeast edge of Hacienda Tepich, are similar in masonry and arrangement. Both apparently had their greatest period of activity before the Late Classic period. Other sites east and southeast of Mérida were located but not investigated.

Mr. Lawrence Roys spent about two months in Yucatán mapping, photographing, and recording several unreported sites and others not adequately described in the literature. One such site, Aké, was visited twice during the field season by Roys and Shook. They were accompanied on the second trip by Proskouriakoff. Historical sources state that in preconquest times the cities of Tihoo (Mérida) and Izamal were connected by a paved road. Remains of the Maya road or *sacbé* were discovered and followed 2 km eastward from Aké in the direction of Izamal. Subsequently Pollock, Shook, and Proskouriakoff traced what is believed to be the same *sacbé* some 6 or 8 km westward from Izamal going in a direct line toward Aké. The road measured 12 m in width and consisted of a dry rock fill between parallel retaining walls of large, roughly cut limestone blocks. This foundation was topped with crushed gravel and smoothly surfaced with lime concrete. That the Maya were competent engineers was evident from the camber given to the road's surface for rapid drainage.

Aké and Izamal are major archaeological sites showing similarity in the orderly assemblage of huge religious and civic structures around rectangular courts, and in masonry and architectural style. Both sites are characterized by masonry of enormous cut blocks with lime mortar between blocks and surfacing of lime plaster. Stucco, decoration often embellished the substructure terrace walls, further obscuring the block masonry. Both Aké and Izamal seem to have completed their major architectural activities before the spread of the Puuc style in the Late Classic period. Puuc type construction, however, was found in several instances to overlie typical block masonry at Aké.

Proskouriakoff spent three days at Chichén Itzá, making a cursory survey of the sculpture which still remains to be photographed. Chichén Itzá sculpture, being the largest body of representative art in the region is a valuable source of background material for the interpretation of late Yucatán history. In many cases, field conditions present difficulties in photography, but it is hoped that a practical plan of obtaining a complete and adequate record can be worked out for a future season.

Proskouriakoff and Shook, on a brief reconnaissance trip to Campeche, investigated two sites along the recently constructed highway between Hopelchen and Campeche. Both sites, Tohcok and Kayal, 4 and 40 km west of Hopelchen, respectively, had served as stone quarries for road construction. Part of a vaulted building remained standing at Tohcok on the north edge of the highway. Photographs, plans, and sections of what remained of the structure, and drawings of the exposed portions of two painted doorway jambs were obtained. The Painted Jambs building, a two-storied structure, originally consisted of lower level of several rooms on each side of a broad stairway leading to an upper range of rooms. Additions from time to time, some apparently to enlarge the second story, required the filling and blocking of the rooms and doorways of the lower level. Eventually the renovations completely scaled and buried the early part of the structure, thus preserving it until recent exposure by road builders. One complete vaulted room remains of the lower story south of the stairway. This room has a doorway in the east and another in the west wall. Each jamb of the latter doorway had been surfaced in ancient times, with fine, hard, creamy-white lime plaster on which was painted in black an elaborately costumed figure framed by a rectangular band of hieroglyphs. The same room has a painted capstone.

The type of masonry and architectural details of the Painted Jambs building and other structures at Tohcok belong to the Late Classic period. The architecture is of neither the distinctive Chenes nor the Puuc style; it appears rather to be a blend of the two. This strongly suggests that Tohcok is a border site between the Puuc and Chenes areas, and that these architectural traditions flourished contemporaneously.

The Kayal site is situated on a low ridge about 500 m south of the highway and village of Kayal. The road builders have left little more than featureless piles of rubble, except for one hieroglyphic stone and one vaulted room of a type found more frequently in the area west of the Puuc region. This type, which may be Early Puuc, is characterized by the use of veneer masonry for walls and upper façades, while retaining slab masonry vaults. Despite the destruction of Kayal, it was possible to trace down and obtain photographs of a considerable number of sculptures from the site. Some were built into the Kayal church, others were in the Campeche Museum, and a number were found in private collections in Mérida.

Two days were spent recording sculpture ceramics, and artifacts in the Campeche Museum. The museum collection includes material from all parts of the state of Campeche. There is an excellent study lot of pottery and artifacts from excavations in Jaina.

South of Campeche, on the Champotón road, surface collections of pottery were made at two previously unreported sites, Queja, 1.5 km north of Seyba Playa, and La Joya, approximately 8 km north of Champotón. Neither site provided evidence of the use of cut stonemasonry or vaults. The sites apparently were occupied in widely separated periods. The pottery indicates that La Joya may be a Preclassic site, whereas Queja appears to be Late Classic or Early Postclassic.

Champotón, identified as the home of the Itzá, and the scene of the earliest armed encounters between Spanish conquerors and natives of the Yucatán peninsula, lies at the mouth of a small river emptying into the Gulf. Native tradition relates that Kukulcan, on his departure from Mayapán, stopped there and that a temple in the sea was erected in his memory. The temple referred to is undoubtedly a small construction still to be seen opposite the mouth of the river on a tiny island almost submerged by water. Two or three well cut blocks of stone remain *in situ*, but most of the foundation is in large amorphous masses of fill, solidified by lime and broken and scattered by the action of the sea. No traces of ancient construction were observed in the town itself, but Shook photographed in a private collection a large sculpture of stone and stucco, representing a reptilian grotesque on the order of those on Altars G and O at Copán, though carved in less elegant style.

The island of Jaina, 36 km north of Campeche, was next visited. Previous explorations by Carnegie Institution [Chapter 1.10] resulting in the discovery of three stelae, one bearing the Initial Series date 9.11.0.0.0, and more recent work by the Mexican Government had shown Jaina to be of considerable importance in the interpretation of Yucatán history. Special attention has been given the site by professional looters in search of the exquisitely modeled clay figurines for which Jaina is now famous. Much of the island's surface is pocked with holes left by the treasure seekers. These cuts into mounds and through plaza levels provided information on construction and subplaza conditions, as well as a large sherd sample.

The site occupies a slightly elevated east-west ridge which is the most habitable part of the small, swampy, low-lying island. Only a narrow estuary separates it from the also swampy, low-lying mainland. From the sea the island would be indistinguishable from the mainland if it were not conspicuously marked by the archaeological mounds. Several large pyramidal structures face east across a series of courts with lesser units to a high pyramidal mound about 200 m distant. The size of the ancient structures, the sculptured stelae, the number of human burials, and the richness of their furniture point to the importance of Jaina and suggest a relatively large aboriginal population. Yet neither

the island nor the immediately adjacent mainland seems to provide sufficient land suitable for agriculture to support more than a few families. Drinking water probably was available from the same freshwater well which now serves the casual fishermen who make temporary stops at Jaina.

Our knowledge of the environment of this region is superficial, and what facts we possess concerning the ruins and their location can be interpreted in several ways. It would appear, however, that the ancient economy must have been based on fishing, the production of salt, the supplying of sea shells, trade in these products, and commerce in general. Agricultural products, pottery, metates, flint, obsidian, etc. would have been brought wholly or in part from outside sources. The famous Jaina pottery figurines most likely were never manufactured in Jaina, but came by trade from some region such as Tabasco. It is important to note that most Jaina figurines are found in graves. A careful search through the back dirt of earlier excavations and over the surface of the site failed to turn up even a fragment of a figurine. The ceramic material known from Jaina places its major occupation in the Late Classic period. Some activity on the island, may have continued into the Early Postclassic period.

40.5.

A. LEDYARD SMITH AND

KARL RUPPERT

Mayapán, Yucatán

YB 51:243–244, 1952

During the 1952 field season, January 17 to May 1, A. L. Smith and Ruppert continued their surface examination of the ruins of Mayapán [Chapter 40.5]. Squares F, G, H, I, O, P, and R were covered this year [Chapter 40.2]. All structures outside the wall within the limits of the map, in squares so far completed, were examined numbered. In the course of the season's work 1,165 buildings were recorded. These, with the 1,143 examined in 1951, leave approximately one-third of the site yet to be investigated.

Every structure seen was given a number, but only those which are of the dwelling type or those associated with such groups were drawn to scale. The structures examined fall into the general categories established, during the 1951 season. Some variations were found,

but no new types. The recurrence of types recorded during the first season, however, their association with one another in groups, and the distribution of these types in various parts of the city are beginning to show a definite pattern. This pattern will undoubtedly become clearer when the survey is completed and a definitive study has been made.

The location of metates, when associated with structures, was recorded. These utensils usually occur on platforms or terraces and are often re-used in construction. The occurrence of carved-stones and Puuc-type building stones was also noted. The latter are found in some quantity re-used in many of the buildings, their presence predominating in the more elaborate structures.

Though the major part of the season was devoted to the examination of the structures mentioned above, several weeks were spent excavating below the floors and benches of house platforms and associated terraces. Bishop Landa, in his *Relación de las cosas de Yucatán*, mentions that the dead were buried in their houses or at the back of them (Tozzer 1941:130). With this in mind, several types of construction were selected for excavation: long, low platforms and houses with two and three benches. Twenty-two pits were sunk in benches, passage ways, back rooms, and terraces in front of buildings. Masonry-lined cists were found under five benches and two platforms. These varied greatly in construction, from a nicely plastered rectangular chamber with corbelled vault to rough, unplastered compartments filled with rubble. Three of these cists had jambs in one end, indicating an entrance below floor level.

In all cases the cists were built at same time as the structure in which they were contained, apparently in preparation for the interment of the occupants of the house. Only in three of them, however, were human remains present. Little grave furniture was recovered with the burials. In one tomb, where there were two skeletons, two pottery figurines, male and female, were found. These were possibly the idols of the individuals buried, in accordance with a custom mentioned by Landa (Tozzer 1941:130).

Until more excavation has been carried on in house platforms, very little can be said about burial customs of common people at Mayapán.

In all instances the latest-type pottery recovered from any dig was of the Mayapán period. It is interesting to note, however, that in one case (Structure J-49-a) Puuc type of pottery predominated.

A rewarding find was a midden under the east bench of Structure J-50-a. From the pit below this bench a quantity of artifacts was recovered in addition to a large sherd collection. Among the artifacts were worked shell and bone (the latter in the form of awls

and needles), obsidian blades, human teeth perforated for suspension, flint implements, a stone metate leg, a miscellaneous animal and bird bones.

40.6.

WILLIAM R. BULLARD

Boundary Walls of Mayapán

YB 51:244–247, 1952

Work of the previous season at Mayapán disclosed the existence of numerous field stone walls running everywhere among the ruins [Chapter 40.2]. Whereas some walls were obviously of post-conquest construction, others were quite clearly contemporary with the occupation of the site. Because many of the latter appeared to surround house structures, it was thought they might delimit property boundaries. During the season of 1952, all the walls in certain representative portions of the site were followed out and plotted on the map. It was hoped that such a study might reveal with certainty the function of the walls and cast light upon land tenure, city organization, and similar problems. Although stone boundary fences around the houses are a regular feature of modern Yucatán villages, they have not previously been reported from a preconquest Maya site.

The walls were completely plotted in roughly one square kilometer of the site, comprising Squares D and K in the north central part and Squares Z, AA, BB, DD, and EE in the southwestern part (Jones 1951). In addition, other areas of Mayapán were reconnoitered in order to estimate the value of additional work.

The entire site is covered by what seems a maze of stone walls, ranging in age from the occupation of the city to the present day. For many years Mayapán was the site of a Spanish cattle ranch, and stone corrals and enclosures were built throughout the central part of the ruins. Moreover, probably ever since the conquest there has been milpa cultivation within Mayapán, as there is today. Finding plentiful stone at hand in the ruined buildings and walls, the Maya farmers often erect stone fences around their fields, not hesitating to repair and re-use older walls when convenient. Centuries of such destruction and rebuilding have confused to a large extent the ancient wall patterns. Relatively few ancient walls are complete, and in many instances only a few sections could be followed. Event

fragmentary walls could usually be related to house structures, but the complete pattern over a large area was all too often obscured. In this respect, the walls plotted in Squares AA and BB proved most satisfactory, since disturbance in those sections has been relatively slight.

Another perplexing problem was that of distinguishing ancient from post-conquest walls. Technologically there are few reliable criteria that can be applied to tell a post-conquest wall from a re-used and rebuilt ancient wall, or an ancient wall from an old and much damaged post-conquest wall. Thus, although many, indeed the majority, could be identified without difficulty, many others had to be marked as questionable. All walls, both ancient and modern, were plotted, by use of different symbols, in the hope that the pattern followed by a questionable wall would give a clue to its origin.

In construction, the ancient walls are essentially alignments of uncut stones set on edge, either touching or placed a few centimeters apart. The average height is 50–70 cm, but some walls are composed of large slabs up to 1.5 m high. In areas free of post-conquest disturbance, the walls often have smaller stones lying near their base, suggesting that the spaces between the slabs were chinked and filled, but the debris was never enough to warrant the belief that the walls rose substantially higher than the stones now standing.

In nearly all instances the walls partly or completely surround individual dwelling-type houses or house groups. Only rarely is more than one house group surrounded by the same wall. Apparently, almost every domestic structure had a boundary wall. In contrast, temples and public buildings such as colonnades do not seem to have been surrounded by these walls, although further checking is needed to confirm this point. The walls ordinarily enclose only enough space for a small yard around the structures. There are numerous variations, but most enclosures are of fairly simple plan, consisting of a rough circle, or rectangle with rounded corners. The houses may be completely encircled or the walls may abut against a house or terrace corner so that they are only partly enclosed. In the more densely settled districts, where space is limited, the enclosures tend to become more irregular, and two neighboring house groups may share a common wall.

Gateways, consisting of a gap about a meter wide between two large stones, were found only rarely. The location of many has undoubtedly been obscured by the collapse of wall stones or by post-conquest rebuilding. Some enclosures, however, could be entered through larger gaps often formed by the overlap of the two ends of the encircling wall. In a few instances the

enclosure may have been reached by passing through the house itself.

There seems little doubt that the walls mark property boundaries around the houses. Evidently each household or group of families had its own fenced yard. This does not, however, necessarily imply that there was private ownership of land in the modern sense. It is quite possible that property was held only by permission of higher authority. Many yards are sufficiently large and on suitable terrain for the raising of fruit trees and small gardens; others include only the tops of the rocky hillocks which were the preferred house sites but which seem unsuited for horticulture.

Nothing was found in the areas plotted resembling a formal arrangement of streets. Passage through the city was evidently accomplished by winding through the gaps and spaces between neighboring boundary walls. Sometimes, particularly where houses are close together, the parallel walls of adjacent enclosures form short, often meandering lanes average about 2 m in width. In one densely settled region in Square AA a particularly complex system of lanes was discovered.

Cenotes are commonly in the areas between house boundary walls and thus accessible to the general populace, as might be expected.

An interesting feature is the small stone circles, averaging 3–5 m in diameter, which are occasionally found near house groups. Some are almost perfectly circular; others are more oval. There is often no gap which might have served as an entrance.

On completion of the detailed examination of the walls in the squares listed above a reconnaissance was made through other areas of Mayapán. In the eastern part of the site several long lanes were found which, unlike the lanes described above, seem to run independently of boundary walls. The most interesting are in the northern part of Square I, where four lanes converge on a small natural depression with three or four steps leading into it, possibly a blocked cenote entrance. Two of the four lanes are part of a series which could be followed in an almost straight line for nearly 400 m through an area in which houses are rather sparse. Additional work will be necessary to clarify the function of these lanes and their position in the over-all settlement pattern.

As has been mentioned, post-conquest disturbance in the areas investigated has been considerable. Although much knowledge concerning the boundary walls has been gained, present information is not clear enough to answer conclusively such specific questions as those regarding the correlation of size of property with size and elaborateness of the house groups, or the relation of the boundary walls with natural fea-

tures such as depressions which could have been used for growing fruit trees. Disturbance seems, in general, to be somewhat less in the eastern part of Mayapán, and it seems certain that further work there will produce much additional knowledge.

40.7.

EDWIN M. SHOOK

The Great Wall and Other Features of Mayapán

YB 51:247–251, 1952

Shook arrived in Mérida from Guatemala on January 13 and returned to Guatemala on May 18, 1952. The major portion of his time in Yucatán was devoted to researches at Mayapán. These included a detailed investigation of the great wall surrounding the ancient city, the partial excavation of two temples, a brief reconnaissance of the cenotes within the walled enclosure and several outside the wall, and study of Mayapán pottery in collaboration with R. E. Smith.

The great wall of Mayapán, first explored by Ralph T. Patton in 1938 [Chapter 1.27] and later by Morris R. Jones [Chapters 40.1, 40.2] now appears as a ribbon of stone rubble meandering over nine linear kilometers through the low, dry, and exceedingly thorny Yucatán bush. In plan it forms a huge, irregular oval with the sharp end pointing slightly north of east. The wall consists of an outer, higher, primary wall and a lower one built against the inner face. This formed a single wall, very thick at the base and stepped at the top, the lower step being a bench, the higher step a parapet.

This wall, representing a vast expenditure of human labor, was built of rough limestone blocks quarried from the outcrops of bedrock nearest the vicinity of construction. The stone was utilized as it came from the quarry, without further shaping or dressing, and laid without mortar. Parallel lines of large stones, placed either horizontally or vertically, formed the wall's facing and retained the core of dry rubble. Presumably the top of the wall, both the parapet and the bench, was capped with a layer of lime cement, though no evidence of this could be obtained, as no part of the wall's entire length was preserved to its original height. Disturbance by tree roots during the centuries has reduced most of the wall to a low line of stone rubble. A

few parts still stand to an average height of 1.5 m; an occasional section where the wall crosses a low area reaches 2 m.

A total of seven major and five minor passages were discovered at intervals in the great wall, and others may have existed formerly. The uncertainty regarding the original number is due to the breaching of the wall in post-conquest times for roads and trails crossing the site. These openings vary in width, and it is possible that some of them obliterated ancient minor passages. One major and one minor gate of the 12 identified had been blocked with masonry during the occupation of Mayapán. This presumably left the remaining six major and four minor gates in use simultaneously. During the field season all these were examined, though only four major gates and one minor one were excavated intensively.

The minor gates are straight, narrow passages about 1 m wide, their floors surfaced with lime cement. The major ones are distinguished from these by a considerable thickening of the great wall on each side of the gateway and by a more elaborate plan. This consists of an entrance about 2 m wide through the wall's outer part, leading to an amplified rectangular space suggesting a portico but still set within the wall. The portico may have one or two columns placed in line with the inside edge of the wall. The placement of these columns suggests that they may have supported timbers for thatch, if the gateway was roofed. The excavation of the lime concrete floors of the porticoes disclosed no debris from masonry vaults or beam and mortar roofs.

Careful search was made in a large area around the gates and within the passageways for indication of ceremonial activities, guardhouses, arsenals, or warfare. No evidence was found of ceremonial pottery dumps, of guard- or storehouses, or of battles at or in the immediate vicinity of the gates. The pottery and artifacts recovered were exceedingly meager in quantity and widely scattered. On the floor within Gate T, at the southeast extremity of Mayapán, however, were discovered several fragments of a thin gold object and a pellet rattle from a copper bell.

Near the same Gate T and just within the great wall of Mayapán are two structures on the southern side of a large cenote, X-Coton. Both these structures were briefly investigated. The western one consists of a terraced, rectangular substructure about 3 m high with a stairway on the north side leading from the plaza level to a single-room temple above. The latter has thin, low masonry walls, which when built probably stood no more than 50 cm high. The temple walls above this may have been of upright wood poles supporting a thatch roof. In the center of the temple room was a roughly circular shaft extending downward

about 1.5 m into the dry rock fill of the substructure. The shaft had been opened in modern times and its contents disturbed and partially removed. We were able to determine from the residue in the shaft that it had been used as a repository for the ashes and charred bones of cremated adults, children, and animals. Mixed with the ashes and bone were fragments of pottery vessels, incensarios, obsidian flake-blades, and flint chips. Some of the pottery vessels once may have contained the cremated remains; but as all were found broken, it is uncertain whether the breaking had been done by the modern looters or by the Mayapán people at the time of burial.

The second structure located just southeast of Cenote X-Coton and nearer Gate T, was investigated more thoroughly. Here sufficient excavations were carried out to remove the accumulated surface debris from the frontal stairways, the summit terrace, and the temples, and to obtain an accurate plan, section, and elevation of the unit and some evidence of its function. This structure consists of a long, low, rectangular platform supporting twin temples. The temples face northwest, and each has its individual stairway with balustrade leading from the general plaza level to the summit of the common substructure. The twin temples differ only in a few details. Each has a single room with an altar against the center of the back wall. Also, each has low, relatively thin masonry walls built of a few large uncut blocks, many roughly shaped blocks and slabs, and some well cut, faced, and carefully dressed stones. These oddly assorted stones were piled up, rather haphazardly, though apparently bedded in a small amount of mud mortar or mud mixed with lime or limestone gravel. This type of masonry appears to be that used in Mayapán most frequently for walls of buildings and facing of substructures, and may be termed "Mayapán block and slab" masonry. The sporadic occurrence of quite obviously reused, well finished stones among the rougher ones has chronological and cultural implications. These stones are readily distinguished from the others by their form and surface finish. They included wall, vault, and plain or decorated cornice stones, and their original use had been in vaulted buildings whose walls were faced with veneer stones belonging to the Puuc style of Late Classic Maya architecture. Remains in this style point to an older period of occupation at Mayapán, long antedating, we believe, the establishment here of a large, important political center. The people responsible for the later city had lost either the knowledge of architecture possessed by their predecessors, or the desire or the economic ability to equal the quality of the older civic and religious buildings.

It was certain from the shallowness of debris covering their floors that neither of the twin temples had

been vaulted. The northeast temple, the larger of the two, contained extremely little debris and probably had been roofed with thatch. Also, because of the wide breadth between jambs, two equally spaced wooden posts must have served as doorway columns.

The smaller, southwest temple may have had a beam and mortar roof. Its floor was buried beneath about 50 cm of fallen masonry, including what appeared to be roof material. This temple had undergone at least five alterations, each marked by the addition of a new lime concrete floor and minor revisions of the masonry altar against the back wall. All these floors and the successive altars, normally white, were severely burned to a grayish black. The frequent renovations of the temple's interior were required possibly by numerous ceremonial fires which smoked the walls and heavily stained the floors. Many fragments of pottery incense burners were found on the surface of the top floor and on the frontal terrace outside. Quantities of the same material also lay on the floor of the northeast temple, on the stairways, and along the base of the substructure, but only on the floors of the southwest temple was there evidence of burning. Over 50 percent of all pottery recovered from the excavation of these twin temples consisted of fragments of incensarios.

A miniature shrine with a narrow doorway was uncovered, centrally placed, at the base of the northeast stairway. Its thin, low stone walls were constructed partly on the plaza floor and partly overlapping the lower steps. No comparable shrine was found associated with the southwest stairway. Instead, in front and on the plaza level, there were three masonry altars placed on the central axis of the temple. The altar farthest from the stairway was the largest of the three. Though considerably damaged in its exposed position, it appeared to be about 4 m square and 50 cm high. Against the altar's edge, facing the temple, a plain, crudely cut stela still stands in its original position. The middle altar, also square and of about the same height, measured 2 m on a side. The one closest to the temple stairway was originally a single circular stone, plastered over and painted bluish green. This altar underwent several remodelings and in its final stage was square. The evidence of much ceremonial activity in the southwest temple, plus the alignment of three altars and a stela in front of its stairway, suggests that this was the more important of the twin temples.

Some attention was given to the cenotes within and immediately outside the walled area of Mayapán. Altogether, 22 cenotes were studied briefly for the purpose of determining which the Maya had used for water supply and which had associated constructions or contained evidence of ceremonial rites. During this investigation it was learned local informants that each

year, generally in the month of August, the people Telchaquillo hold a rain ceremony at Cenote Itzmal Ch'en, the most easterly one inside the Mayapán wall. Here, 3 km from their homes, secluded beneath several fine shade trees overlooking the beautiful cenote and surrounded by ruined temples and houses of their forefathers, the living Maya still call on their gods of the forest, the winds, the milpas, and especially the rain to aid the young corn to grow strong and produce abundantly. All females and children are excluded from this solemn affair. Each man contributes an equitable share of the money, alcoholic beverages, candles, turkeys, chickens, corn, and other items demanded by the professional shaman, who is hired from the town of Tecoh to conduct the ceremony. The ritual begins at sunrise on the appointed day and continues without interruption until the afternoon of the second day. During this long period no one is permitted to sleep. There is no music or dancing. Everyone present must perform the tasks allotted him by the shaman. Water has to be drawn from the cenote, wood gathered for the many fires, pits dug and stones collected for a special method of baking, food and drink prepared, and so on. The shaman sacrifices the turkeys and chickens, and ceremoniously cuts the fowl into small pieces on a flat-topped, rectangular stone. Some of the food is cooked in pots resting on three stones over an open fire. Other foods are baked; this is done by placing the food on banana leaves laid over preheated stones inside a pit, covered with more leaves, then earth, and allowed to bake for several hours. According to one informant, before the food is eaten it, is blessed by the shaman, who tosses bits of it into the cenote as an offering to the gods. Much drinking accompanies the entire affair.

This ceremony, called *Cha chac*, is directed expressly toward the rain gods to assure that rains will come at the required time to benefit the young, growing corn. The informants stated that it is not just a local custom, but all the neighboring towns and villages practice the ritual. Each community has its own particular place in the forest near their village where the ceremony is held. Only the people of Telchaquillo use the site by Cenote Itzmal Ch'en.

Pottery and artifacts were recovered in varying amounts from all excavations in Mayapán. Discussion of the ceramic material is presented by R. E. Smith, and of the artifacts by Proskouriakoff. Very little pottery trade material came to light during the past season. A type of Fine Orange was the only imported ware that consistently appeared in most of the excavations, though in very small amounts. More widespread trade was evident from the artifacts of stone, shell, and metal. The first included jade, obsidian, and greenstone; the last, gold and copper.

During Shepard's stay in Yucatán two short journeys were made with her to study present-day methods of making pottery. The first trip was to the village of Mama, 18 km south of Mayapán; the second to Maxcanú, a town southwest of Mérida on the railroad to Campeche. At both places samples of the raw materials were obtained and the techniques employed by the potters were observed, with the thought in mind that the clays, tempers, and methods still in use might be similar to those found in the preconquest pottery of Mayapán. The Maxcanú potters stated that their tempering material was quarried locally, but clay had to be brought in by trade from a source near Becal and Tepakan. The potters from the latter towns obtained tempering material from Maxcanú.

Another of the Department's research objectives in Yucatán is the study of archaeological sites occupied at the same time as Mayapán. Historical sources indicate that most of the contemporary towns in northern Yucatán were subject to the political authority of Mayapán. How closely the remains of such towns conform to those of the capital is not known. Certain features such as house plans and grouping, types and architectural style of public buildings, styles of sculpture, pottery, and other artifacts may often be observed without excavation. These data serve to indicate with some degree of accuracy the conformity or nonconformity with the type site.

Reports of ruins obtained verbally from the local inhabitants were investigated whenever possible. Those in the environs of Mayapán received more attention during the past season than sites elsewhere in of Telchaquillo, the peninsula. The ruin over which the modern town is built, are 2 km north of Mayapán. Some of the house mounds scattered around Telchaquillo have plans similar to those of Mayapán, but other house mounds and the larger ceremonial structures appear to predate those of the type site. Just 2 km due south of Mayapán a minor group of ruins surrounds Cenote Mateyac, and these belong to the Mayapán Period. At Cenote Itzimkan, 6 km to the northwest, there is another site, the architecture and pottery of which indicate occupation, perhaps continuously, from the Classic through the Mayapán Period.

Mr. Lawrence Roys and Shook returned to the ruins of Aké [Chapter 1.40] and spent three days in further study of this important site. The combined results of their investigations will be published in a forthcoming report. An outstanding discovery pertaining to this site and to Izamal was made by Sr. Victor Segovia, of Mérida. Acting on our suggestion, he undertook the difficult task of following the ancient roadway, or *sacbé*, from Aké to Izamal, a distance of approximately 32 km. He thus confirmed the previous surmise that the great road connected these sites. Along the way Segovia

noted two previously unreported ruins, Xemná, and Sitpach. Xemná, a site of 20 or more mounds, 7 km east of Aké, was connected with the ancient highway by a branch sacbé 9 m wide, even though the ruins lay only 150 m to the north. Farther east, on Hacienda Muycuyche, was the minor site of Sitpach, consisting of a few scattered mounds along the south edge of the sacbé.

40.8.

ROBERT E. SMITH

Pottery of Mayapán

YB 51:251–256, 1952

During the first month of the 1952 field season, R. E. Smith completed the selection of Yucatán sherd collections to be sent to various institutions in Mexico, Guatemala, and the United States [Chapter 1.40]. These collections include wares and types classified on the basis of descriptions by Dr. George W. Brainerd and R. H. Thompson. They contain material from Acanh, Chichén Itzá, Cobá, Dzibilchaltún, Holactún, Kabah, Labná, Maní, Mayapán, Oxkintok, Sayil, Uxmal, and Yaxuná.

The greater part of the season was spent in investigating Cenote X-Coton, in the southeast corner of Square T at Mayapán [Chapter 40.2]. This location was selected because of the apparent importance of the cenote in prehistoric times. The position of two ceremonial structures and a major-gateway in the city wall in relation to the cenote, as well as the presence of artificial constructions on the floor of the cavern, suggested that the erstwhile inhabitants of Mayapán laid considerable stress on this natural feature.

X-Coton is a jug-shaped cenote with a banana grove on the stretch of floor that lies below the rather large, circular opening. The opening is eccentrically located over the southern part of the cavern, the northern part being roofed by natural rock. The cenote is, or was in ancient times, a source of water.

Of particular interest and prominence was a platform, more or less centrally located on the floor of the cenote, approximately under the northern edge of the opening. This wedge-shaped structure was mounted by a stairway at the narrow western end, the blunt eastern end being rounded. To the north of the platform there descended to a lower level an artificially

constructed stairway, almost completely covered by dirt and bat dung. This refuse was cleared away, revealing 18 steps and a clear pool of water at the bottom.

The platform, presumably ceremonial in function, was cleaned and tested but not completely excavated. A trench dug to bedrock at the eastern end of the structure revealed the fact that the foundations were of large and medium-sized stones that included a small amount of pottery of both Puuc and Mayapán Periods (Table 40.8.4, D-4, D-5, D-6, D-18). These foundations rested on a leveled fill of dirt nearly 1 m deep that also contained Mayapán and Puuc Period sherds, and a sizable representation of Classic Period and Regional Polychrome pottery (Table 40.8.4, D-8, D-11, D-15, D-16, D-17).

Neither from the trench east of the platform nor from a pit sunk in the floor of the cenote at the center of the banana grove (Table 40.8.4, D-10) did chronological stratigraphy materialize. At all depths there occurred Mayapán Period sherds mixed with those of the Puuc. Surface sherds were collected throughout the cenote to a depth of 10 cm (Table 40.8.4, D-2). These, as might be expected, were largely of the Mayapán Period.

During the gathering of the surface sherds, two natural recesses, or niches, in the wall of the cenote were encountered and excavated. This resulted in the discovery of a sculptured stone dog and run-of-the-mill pottery in one niche (Table 40.8.4, D-20) and a sculptured squatting human figure associated with a large quantity of censer fragments in the other (Table 40.8.4, D-9).

Four caves were noted during the examination of Cenote X-Coton. These occur as subsidiary caverns in the peripheral wall of the cenote. Only two could be excavated, the others being either too narrow or too shallow for anyone but a small child to enter.

Cave 1 was the more interesting. It had been used for what appeared to be secondary burials, possibly in pre-Mayapán Period times. The cave was deep, extending down to water. The lower section was filled with small and medium-sized rocks. Above this, skeletons were found along with many broken vessels of both coarse and fine wares, most of which were of the Puuc Period style, but an appreciable percentage of which were Classic Period and Regional Polychrome (Table 40.8.4, D-7). A single whole vessel of medium paste slate was recovered. Since it is presumed that the skeletons together with their pots were added at different times, rocks being tossed in to cover them, it is not surprising that the bones were spread over the cave and the pottery was smashed. The action of dripping water of high lime content tended further to obscure the picture, since it cemented the bones to one another and to the rocks.

A small percentage of Mayapán Period sherds was found mixed with the rest of the pottery and bones. No very satisfactory explanation for the presence of these late sherds has been advanced. It is, of course, possible that one or two Mayapán Period individuals were buried there. Actually, the arm bones of one skeleton, just below the top stones, appeared to have been articulated, suggesting that the last burial was primary.

Cave 2 was of less interest. It harbored a few sherds (Table 40.8.41, D-14), mostly of the Mayapán Period, and a single skeleton in poor and fragmentary condition. This cave was like Cave 1 in containing a layer of small and medium-sized stones below which the sherds and skeleton were found. It differed, however, in having a deep carpet of bat dung. No bats were noted in Cave 1, but they occurred in great numbers in the second cave.

An analysis was made collected from house platforms by Ruppert and A. L. Smith (Table 40.8.1). Twenty-six platform cuts resulted in only 3,628 sherds, an average of about 140 sherds per cut. Two major ceramic periods were indicated, the later and the more abundant (92.6 percent) being the Mayapán Period, the earlier (4.5 percent) the Puuc Period. Elements of two other ceramic periods were present: the Classic Maya, represented by Regional Polychrome (0.03 percent), and the Toltec, exemplified by Fine Orange and Plumbate Wares (0.53 percent). Only two Plumbate sherds were found at Mayapán, whereas there were 83 specimens of Fine Orange, mostly of a new Mayapán type but with rare occurrences of X and Z.

The excavation that produced the purest Mayapán Period remains was made in Structure J-50-a, where, save for one Fine Orange body fragment, all sherds belonged to the Mayapán Period (Table 40.8.1, A-13). This cut penetrated a midden which contained, besides pottery, all sorts of bone, shell, obsidian, and stone implements and ornaments. Only one excavation in a house platform yielded a greater percentage of Puuc than of Mayapán Period pottery (Table 40.8.2, A-12). This was in Structure J-49-a. The entire platform had an unusually large percentage (404) of Puuc Period sherds. It would seem from the limited information so far available that house platforms at Mayapán normally were late constructions containing Mayapán Period sherds in the fill. When Puuc Period, pottery is the more abundant, as in the above instance, a nearby refuse dump or occupation area of that period is indicated.

On the suggestion of Ruppert and A. L. Smith, a trench was cut into the north side of Structure J-49-b, a house platform. The trench advanced at bedrock level, encountering first the north terrace wall, then a rough retaining wall, and finally ending against a plastered tomb without skeleton or furniture. There being no

obvious strata, three more or less arbitrary levels were maintained throughout the trench. The ceramic findings in these levels and between walls did not vary appreciably (Table 40.8.1, A-6, A-7, A-11, A-18, A-19, A-20), the percentages of sherds from all the cuts being as follows: Mayapán Period, 95.7, Puuc Period, 2.1, Unidentified, 1.4, Fine Orange, 0.8. Thus, our attempt to find significant stratigraphy was not successful.

A tabulation by periods or wares of the pottery from four city gates and from several ceremonial structures excavated by Shook is included in Table 40.8.2-3. Two cuts associated with Gate T produced unusually high percentages of Puuc Period sherds (Table 40.8.2, B-4, B-5), whereas the ceramic material; (over 50 percent censers) from the nearby ceremonial structures is preponderantly Mayapán Period (Table 40.8.3, C-2, C-3, C-5).

The work of the past season at Mayapán leaves us with an intriguing ceramic picture and a serious problem. So far there is every indication that two major ceramic periods existed at the site: the Puuc and the Mayapán. Just where the Puuc-style pottery fits into the chronological sequence is not clear, owing primarily to the lack of recognizable stratigraphy and to the fact that Dr. G. W. Brainerd's extensive study of peninsular ceramics is not yet available. Together with the Puuc Period pottery are frequently found types called by Brainerd Regional Polychrome. This pottery is the same macroscopically as that found in the Petén in both the Early and Late Classic Periods, but more often in the Early Classic. Fine Orange sherds, some 83 in all, plus two Plumbate fragments, suggest a Toltec horizon, although the chronological implications of the former ware are still far from clear. If Mayapán had been occupied in Toltec times, however, there should be more wares than Fine Orange and Plumbate to represent that period. Is it possible that a portion of the seemingly Puuc-style pottery is actually of Toltec Period, or should certain Mayapán Period ceramics be assigned to Toltec times? The latter seems the more likely, but much investigation is necessary before the situation will be clear.

40.9.

TATIANA PROSKOURIAKOFF

Sculpture and Artifacts of Mayapán

YB 51:256–259, 1952

Although according to native histories Mayapán was “founded” by the hero Kukulcan, whose name is associated with the cult of the feathered serpent, even from surface remains it is clear that in fact city is older, and that long before its reputed “founding” it was occupied by a people with traditions like those of the Puuc. No building of this earlier period has been identified, but everywhere, in surface debris and built into walls of a cruder masonry, one can find accurately cut and smoothly faced stones, as well as, carved elements of decoration almost identical with those of the most elaborate buildings at Kabah and Uxmal. These stones are cut from carefully selected, smooth, hard limestone, and the relief of their carving is still sharp and clear. There are elements of masks and carved moldings, spools, crosses from the lattice motif, and other forms familiar in the Puuc. In addition, there have been found

three excellently carved human heads, distinctly Maya in their features, and designed to be tenoned into masonry construction.

Fragments of stelae with inscriptions, of which there are several, also probably belong to this earlier period. Dates have been suggested for some of them, but none are sufficiently legible to merit acceptance. On the other monuments, apparently similar in design to those with inscriptions, glyphs are blocked out but left blank of detail. Stela 1, now in the hacienda at Xkanchakan, is the only low-relief stela on which figures can still be made out. In design it differs from Classic Maya monuments. The relief is flat, the detail is executed in lines only, and the composition is divided into panels, one containing glyph blocks, and the other an arrangement of figures suggestive of a scene from a codex. The largest stela of this type lies at

the base of a round building on the east edge of the main ceremonial group. It is carved of very poor limestone filled with fossil inclusions of shell; its position, the choice of poor material, and the omission of glyph details raise the question whether the stela cult did not still survive in the later period of Mayapán.

Most of the monuments associated with the late remains are carved of the same coarse-grained, shell-filled limestone, which erodes unevenly, so that much detail is lost and the original quality of the carvings is difficult to judge. As a group, these sculptures are different from any other known group in Yucatán. So far, no attempt has been made to define the style or to trace its antecedents. The work this season consisted mainly in completing and supplementing the record previously made by Andrews [Chapter 15.5] and others of the sculptures, which are concentrated in the main ceremonial group. In the course of this work, the remains of a very low round platform with rectangular additions were discovered in the plaza north of the Castillo. A number of carved monuments and fragments of plain stelae were scattered on and around this platform.

Certain features of late sculpture at Mayapán derive from the Toltec tradition. Among these are carved serpent columns and banner holders in the form of squatting figures. The serpent columns are more crudely executed than those at Chichén Itzá. The shaft is plain, and the heads of the serpents are separate elements. The design was probably finished in stucco. The banner holders are animal figures, with heads turned sharply to one side in the manner of Chacmool statues. No Chacmool has been found, but perhaps this is not significant, for at Chichén Itzá they were often buried in construction. Mayapán, however, clearly lacks the rich low-relief carvings of warriors, priests, and processions, and the carved altars and Atlanteans that distinguish Chichén Itzá. Two low-relief figures of monkeys, found on a mound outside of the main group are of crude workmanship. A very late date is suggested for them by what looks like the Mexican sign *tecpatl*, a flint knife with the features of a skull, behind one of the monkeys.

The principal carvings of the Main Group are figures of somewhat less than life size, in full round or in three-quarters relief. Though some are carved on all four sides, they tend to retain a block-like character, with stronger modeling on the front and sides than on the back. A number have round depressions on top of the headdress. Other figures have a tenon extending part way up the back, as if they were set into masonry. One such figure was found on top of a mound in a position which implied that it once stood in a shrine. These figures are clearly not stelae, nor can they be regarded merely as elements of architectural decoration. They may be the idols which Kukulcan is said to

have introduced into Yucatán in late times. Several squatting figures resemble in a general way the numerous idols of Mexico, and one excavated in Cenote X-Coton is undeniably an idol. The eroded condition of most of the figures precludes a detailed study of their dress and accouterments, which otherwise might furnish a clue to their origin or stylistic affiliations. Both Maya and Mexican traits can be recognized in the surviving detail, but there is not enough to define a complex of traits.

Several other forms seemingly peculiar to Mayapán were observed, but because of the very poor condition of the sculptures found on the surface, a full description is postponed in the hope that future excavations may bring to light better-preserved examples to enable us to classify and evaluate the material more fully.

Any sound appraisal of the sculpture of Mayapán is further hindered by our very imperfect knowledge of the history of sculpture elsewhere in Yucatán. Architectural and ceramic studies indicate that there was a strong and uniform tradition centered in the Puuc region, which at one time spread widely over the northern Maya area. This condition does not seem to be reflected in figure sculpture, which shows bewildering variability. Without a basic chronology of styles to which one can refer, untangling the complex maze of influences and relationships which the Yucatán material implies is a formidable, perhaps an impossible, task. At present, studies limited to variations within definable types or styles of sculpture offer more chance of success than does an attempt to cover the whole field. A classification of mask elements and other architectural motifs, with particular reference to the technique of carving and assemblage, may help us to relate the earlier occupation of Mayapán specifically to individual sites and possibly to a limited period in the Puuc style. A start at gathering together such material was made last fall. A similar study of serpent heads may also prove worth while.

A broader, field of interest can be served by a comprehensive study of the low-relief sculptures at Chichén Itzá. Although this is the best-known body of sculpture in Yucatán, many of the reliefs remain inadequately recorded, and the material has never been studied as a whole. The absence of comparable sculpture at Mayapán poses interesting questions in regard to the chronological and cultural relations between the two cities. Once the chronology is established through ceramic and architectural sequences, the sculpture of Chichén Itzá may become a more valuable source of data on the ethnography and history of Mayapán than are its own inferior sculptures.

The first *desideratum* is a more complete record than we now have of all exposed low reliefs at Chichén Itzá, particularly those depicting human activities.

With a view to determining whether a project to obtain such a record is feasible, and what work and equipment it would involve, Pollock and Proskouriakoff spent several days at the site listing sculptures of which it is desirable to have photographs. The estimate of the number of negatives necessary to cover unrecorded or poorly recorded sculpture is approximate, since this number depends on the type of equipment used and the degree of success in obtaining good lighting for extended areas. About 1050 negatives was estimated as the minimum needed to cover the material actually examined. To this should be added perhaps another 100 for sculptures in several outlying structures which were not visited, and a margin for duplication and spoilage. Many of the subjects require night photography with artificial lighting. In a small number of cases, the use of scaffolding seems necessary.

In addition to the bas-reliefs, there are many figures of Atlantean type at Chichén Itzá not thoroughly recorded. These, being more formal in design, offer fewer ethnographic data. Of more immediate relevance to our studies are minor full-round figures, which have largely escaped attention. It is possible that among aberrant and eroded figures at Chichén Itzá and in the Puuc there are some comparable to the Mayapán idols. A systematic search for them would hardly be advisable at this time, but a review of the known material in the light of what is found at Mayapán may give evidence of late occupation where we do not suspect it.

More than 200 artifacts from Mayapán were catalogued this season. Some came from, a surface collection made by Morris in previous years, many more were gathered by Bullard this year, and others were found in excavations. Among the artifacts are a number of tools of native limestone, most of them articles of household use, others, such as stones for smoothing plaster, being the implements of artisans in building and other trades. There were 83 chipped flints of various forms, differing widely in quality of workmanship. Most were coated with a deep white patina. Among the specialized forms were two sacrificial knives like those recovered from the Sacred Cenote at Chichén Itzá, a number of small hatchet-form and triangular tools of unknown function, and a variety of knives and projectile points. Two very small points may have served as arrowheads, but the only arrow point of specialized form so far recovered was a small, delicately chipped point of obsidian, excavated by Shook.

Obsidian occurred in quantity, mostly in the form of thin flake-blades. Its color is translucent gray, often heavily streaked with a darker tone. A used core intimates that the material was imported unworked, and that the flaking was done locally. Most common among other artifacts of imported stone were small polished celts of dark greenstone. Several jade beads and an ex-

quisitely carved small pendant in the form of a human head were discovered by Shook in his excavations.

Other materials included pottery, shell, bone, antler, and coral. Perforated teeth, both animal and human, were apparently used in necklaces. Several very small flakes of gold and a tiny ball of copper, probably from a bell, established the presence of metals. The collection is still too small to represent the whole range of artifacts we may expect to find at Mayapán. The present material, therefore, after being catalogued and, in part, photographed, was stored for future study.

KARL RUPPERT AND
A. LEDYARD SMITH
Mayapán, Yucatán

YB 52:256–257, 1953

The greater part of the 1953 field season, January 16 to May 10, was spent by Ruppert and A. L. Smith at the ruins of Mayapán. Although most of their time was occupied with the continuation of their surface examination of the ruins, started in the 1951 field season and carried on through 1952 [Chapters 40.3 and 40.5], several weeks were devoted to excavation at Mayapán and exploration at three large sites in the Puuc region of Yucatán.

During the season Squares Q, S, T, W, X, BB, DD, and FF were covered, leaving Y, Z, and AA still to be done to complete the surface examination (Jones 1952). This year 1,019 buildings were inspected. With the 2,308 structures examined during the two previous seasons, this leaves about one sixth of the site still to be examined. Following the system used in the earlier field seasons, all structures were given numbers, but only those of the dwelling type, or those associated with groups of the dwelling type, were drawn to scale. No new type of dwelling was found, but when a particularly interesting building or group was encountered it was noted for possible future excavation. The presence of house-type structures in the main ceremonial group, a custom thus far unreported in the ceremonial sites of the southern area of the Maya, is of interest. It may be that they are late constructions.

Again this season the location of metates and the presence in buildings of stones typical of those used in Puuc architecture were recorded. The common metate found at Mayapán has no legs; several fragments of metates with legs were found, however, in excavations in the fill of structures. These metates were invariably of volcanic stone, which is not native to Yucatán, thus marking them as imports in the area.

Three of the larger houses with three passageways leading from the front room to the back room were chosen for excavation, and pits were sunk in the benches, passageways, and front and back rooms. Two of these houses each had a shrine room behind the center of the otherwise back room. In one structure there were two subfloor chambers. A stairway led down from the front room to a small antechamber leading into the main subterranean room, which had a bench along the wall opposite the entrance. Both chambers were roofed with corbelled vaults. Unfortunately these rooms had been robbed at some earlier date and nothing was found in them. There is little doubt, however, that they were built for burial purposes. In one of the other two houses, four skeletons were found buried in the fill under the floor of the central passageway; in the other, the skeleton of a child was found in the fill under the central passageway, parts of three skeletons below the floor of the back room in line with the central passageway, and eight under the floor of the shrine room.

Another structure excavated was a shrine located near the center of the court before one of the three houses mentioned above. It originally was a small single-room building with a doorway facing west toward the principal structure of the group. Later another room, or shrine, was added to its south side. The latter had an entrance at the south, facing a stairway leading from ground level to the elevated terrace that supported the group. Both shrines had secondary benches against their back walls. A pit through the bench and floor of the north room uncovered a small, roughly rectangular tomb built of stone and covered with three stone slabs, and containing a single skeleton.

Little grave furniture was found with the burials uncovered. In one instance a pottery figurine of a woman was unearthed. All the pottery recovered from the various pits dug included sherds from the Mayapán period. A trench off the side of one group disclosed a fair amount of midden material, as did one of the pits sunk through the floor of a house. The finding of a good number of fragments of human effigy incensarios in the shrine room at the back of one of the houses suggests the practice of worshiping household idols. An interesting find was a small stone head of Olmec style under the floor of the shrine mentioned above.

At the end of the season several weeks were spent at Uxmal, Kabah, and Sayil investigating, house-type structures. Through the kindness of Dr. Alberto Ruz Lhuillier, Ruppert and Smith were able to stay at the archaeological quarters of the Instituto Nacional de Antropología e Historia at Uxmal. At that site 33 houses were examined and drawn to scale. At Kabah and Sayil the availability of maps by Shook greatly aided, the work. Fourteen structures were drawn to scale at each site. The houses at all these sites, as at Mayapán, were found associated with ceremonial groups as, well as away from them. With the exception of a type of long single-room building with a bench around three sides, at Uxmal, they differed in plan from the Mayapán house structures. The Puuc dwellings are single-room buildings, each with a doorway in one wall, or structures of a series of adjoining single rooms each with its separate doorway.

At Uxmal a portal vault, hitherto unreported, was discovered about 3 km south of the great pyramid known as the Adivino.

WILLIAM R. BULLARD

Property Walls at Mayapán

YB 52: 258–264, 1953

Most of the 1953 season was spent in continuing the study of the property-wall system at Mayapán [Chapter 40.6]. Complete plots were made of the walls in Squares H, and Q [Chapter 40.2]. In addition, other parts of the city, previously unvisited, were reconnoitered. Several small excavations were undertaken in order to investigate certain features of the walls and related structures which were not apparent from surface observation.

At the close of the 1952 season, it was concluded that further plotting would be, desirable in order to give a more adequate sample of the complete wall pattern over a wide area (Bullard 1952). Squares H and I in the eastern part of Mayapán were selected because there was apparently relatively good preservation of the walls in this region. Moreover, these squares contained other features of special interest. The Itzmá Ch'en ceremonial group in Square H offered an opportunity to study the wall pattern as it related to structures of clearly nonresidential function. In Square I,

the presence of certain long lanes, which seemed to run independently of the house property walls, required detailed investigation.

As expected, a reasonably clear wall pattern was obtained for the two squares. There was abundant confirmation of the principal conclusions of last season's work. Nearly every house or house group was surrounded by a stone slab or boulder wall. The dwelling unit thus surrounded could in almost all instances be anticipated from the map of the ruins. An isolated house structure, for example, would generally have its own walled enclosure, as would a group of two or three individual house structures standing in close association with each other, usually on a common terrace. Although variation occurred, the enclosures most often were roughly circular or rectangular in plan and included only enough area for small yards around the houses. There seems little doubt that the walls actually did mark the boundaries of the properties belonging to the houses. Where house properties were close together, there were often narrow lanes, formed by neighboring property walls, which provided routes of access. Gateways could be identified only rarely. Probably most were simple, narrow gaps that have been obscured by subsequent toppling of the wall stones.

Little new information was obtained concerning the construction of the walls. The bases of several walls standing in relatively deep soil were cleared. It was hoped that the accumulated soil might have preserved some feature of construction that would otherwise have been destroyed, but nothing new was discovered. Construction was of the simplest. The slabs and boulders forming the walls were merely tilted upright and braced with smaller stones as the nature of the terrain or the shape of the stone required. The stones averaged about 50 cm to 1 m in height, 40–80 cm in length, and 30–40 cm in width. The interval between the large stones were in most instances probably chinked; sometimes debris is sufficient to suggest that the wall may have been carried up slightly higher than the stones now standing. Some of the debris surrounding the bases of the walls is probably the result of spalling caused by milpa fires.

During the wall plotting certain very fragmentary sections of wall were encountered which seemed to make little or no sense in terms of the over-all wall pattern of the area in which they occurred. A number were found near the northwest corner of Square I in an area which also included the poorly preserved remains of several small house platforms. Yet in close proximity to those poorly preserved platforms and walls were several well preserved houses and property walls. It seems possible that the destruction took place in ancient times and that certain structures and walls were robbed of stone for use in nearby houses.

No ancient walls are associated with the ceremonial buildings at Itzmal Ch'en. A wall circled around the southern half of the cenote opening, but the area around the ceremonial group, from the cenote to the gate in the Great Wall east of Itzmal Ch'en, was evidently free of walls. Except in three instances, house groups bordering this area had property walls. These three are not distinguishable in either size or construction from the common run of houses throughout Mayapán, but their unusual lack of property walls, coupled with their proximity to the ceremonial center, suggests that they served some special purpose in connection with the center.

Of particular interest were the two long lanes running east-west across Square I. They are formed by two parallel walls about 2 m apart, and in appearance resemble the shorter lanes often formed by adjacent property walls. They are unusual because of their great length and because, in the main, they seem to run independently of house property walls. An occasional house, however, may use a section of lane wall to mark one side of its property. The northern lane, discovered during the 1952 season, starts near the west edge of the square and continues eastward for 400 m, coming to an end about 100 m southwest of Cenote Itzmal Ch'en. The southern lane winds across the square in southwest-northeast direction and joins with the northern lane a short distance before its eastern terminus. Both lanes tend to follow low areas and seem to be laid out so as to avoid already existing house properties, a fact suggesting that they are relatively late constructions.

The location and direction of the lanes suggest that they served as through routes to Cenote Itzmal Ch'en and its nearby ceremonial group. The eastern terminus is only a short distance from this large cenote and there are no intervening walls to impede passage. The western terminus of each lane seems to be near the west edge of Square I. Attempts to trace these lanes in the adjoining square farther to the west were unsuccessful.

A test trench across the northern lane at a point where it crossed a low area with relatively deep soil revealed a pavement composed of unshaped slabs and small stones. Since this area would be very muddy in wet weather, the pavement was undoubtedly intended to provide a dry footing. For much of their length the lane walls are set directly on bedrock.

A few short lanes branch off from the two long ones. At least one short lane leads to the stairway of a nearby house group, and another may do so. Near the center of the northern long lane, two shorter lanes converge from north and south, respectively. At their junction is a small cave with steps leading into it. On investigation this proved to be the entrance to a cenote

which had been blocked within recent times, presumably by local farmers. The entrance was cleared and a natural passageway, in which stone steps had been laid, was followed to water. The lane leading south from this cenote joins with the southern long lane; the one leading north could be followed only about 60 m. The association of the cenote with a lane junction is good indication of its importance as a water source for this part of Mayapán.

In an attempt to gain further information concerning the relation of the property walls to ceremonial and public buildings, and also to see if there was a different pattern of walls around house structures located close to the principal ceremonial group of Mayapán, a complete plot was made of the walls in, Square Q. The results of much of this work were disappointing. Square Q is covered by a network of walls of unquestionably post-conquest origin, and the ancient walls were found to be so fragmentary that little in the way of a coherent pattern could be determined.

The great number of modern walls attests the intense farming and ranching activity to which this part of Mayapán must have been subjected from the colonial era on. The size and shape of the enclosures made by many of these walls suggest they were milpa boundaries; others were evidently cattle enclosures connected with Rancho San Joachim, located in the northern part of the square. The modern walls were laid with no regard for the location of ruined buildings. Nearly every modern wall crosses ruins; some even cross large temple structures of the Main Group. This entire group and a considerable area about it are boxed in by the high wall of a large cattle enclosure which was part of the ranch. Since this wall cuts through a number of other post-conquest walls; must be of relatively recent date.

The construction of so many modern walls is the principal reason for the fragmentary condition of the old property walls. Stones were taken and the direction of old walls altered when they were incorporated into later walls. Very likely parts of some old walls were demolished because they interfered with the uses to which the modern enclosures were put. Although the complete pattern of the property walls in Square Q cannot be reconstructed, certain important conclusions can be reached from study of the remnants of those walls. Thus, with certain exceptions to be considered below, the Main Group is free of property walls. Excavations there have disclosed occasional low walls of shaped stones which apparently mark the limits of plazas or ceremonial precincts, but these do not seem comparable either in construction or in function with the rough boulder and slab walls which are omnipresent throughout the residential areas of Mayapán. From these data together with those from Itzmal Ch'en and the small ceremonial group at Cenote X-Coton, it

is safe to conclude that the temples, shrines, colonnaded halls, and other clearly ceremonial or public buildings of Mayapán did not have what we are calling property walls. The latter seem to be almost exclusively associated with residential buildings.

Outside the Main Group proper, Square Q contains a dense concentration of ruined buildings. Many are ordinary house structures of the type found everywhere throughout the city. There is also a liberal scattering of groups which are larger and more elaborate and where we suspect the more important residents of the city lived. Remnants of property walls occur throughout this presumed residential area. It was hoped that some correlation could be made between property-wall patterns and elaborateness of house groups, but the fragmentary condition of the walls rendered this impossible. From data collected elsewhere in Mayapán, there are suggestions that some of the larger groups may not have been enclosed completely by property walls, but may have been only partly surrounded.

It was noticed, particularly in the south part of Square Q, that as one approaches the Main Group remnants of property walls become scarcer. Many house groups, both simple and elaborate, have no trace of property walls. It is improbable that this is due entirely to post-conquest wall building. There are no more modern walls near the Main Group than at the peripheries of the square. Moreover, it is unlikely that every trace of an ancient wall would be destroyed; at least some the larger stones should remain. In fact, a few relatively long sections of ancient wall are preserved in close proximity to large modern walls. All in all, it appears that many houses near the Main Group had no property walls. Furthermore, the scantiness of the wall fragments that do remain suggests that the pattern of property walls and the function of apparently residential structures in this part of Mayapán may have been somewhat different from that found throughout the most of the city.

A notable feature of Square Q is the dense concentration of buildings. House structures are found immediately outside the plazas and courts of the main ceremonial group. Most of them are of the simpler types of Mayapán house construction. Perhaps many were the quarters of caretakers or attendants who worked in the Main Group. A few, however, are so located as almost to suggest a late encroachment of house structures into primarily ceremonial areas. One example, Structure Q-91, is located on the north edge of an area otherwise surrounded by colonnaded halls and temples. South of this structure is a segment of wall, seemingly part of a property wall belonging to the house, which arcs through part of the area and further suggests encroachment.

Another small house structure, Q-86, is built against the east wall of a large colonnaded hall, Structure Q-99. The latter faces west on a court, so the house is built against its back wall. A section of property wall seems to circle around the north and perhaps the east end of the house, one end coming to within a meter of abutting the northeast corner of the larger structure. The plan of the wall suggests that it belonged with the house, and that the back wall of Structure Q-99 provided one boundary of the enclosure. Because this situation was unique because it was the closest thing to direct association of a presumed property wall with a ceremonial structure, it was decided to excavate in an effort to determine the chronological relations of the house, the wall, and the ceremonial building.

No excavation was made within Structure Q-99, but trenches were dug along its back wall, in order to locate the junction with the house platform, and trenches were also dug outward and along the property wall. These excavations disclosed a complex series of constructions which were not at all apparent on the surface, including a buried ash- and marl-filled platform north of Structure, Q-99. Although time did not permit the extended excavations necessary to obtain a complete picture of the sequence of construction, it was clear from superpositions of construction and changes in associated pottery that the house platform and the wall were the latest in the sequence and that they had been built later than the substructure of the colonnaded hall. There is no reason to believe, however, that Structure Q-99 did not remain in use after the house structure had been built. A striking feature of the excavation was the large amount of domestic refuse, utilitarian pottery, obsidian blades, animal bone, and so on, and the scarcity of sherds from figurine incensarios, which are ordinarily so abundant around ceremonial buildings. It indicates that the house structure, despite its location, did in fact have a domestic function.

The work of the 1952 and 1953 seasons disclosed the existence throughout Mayapán of a number of small circular or oval enclosures 2 to 5 m in diameter, constructed of large slabs in exactly the same manner as the property walls. They are generally located close to house platforms but are by no means a regular feature of the Mayapán houses. Search was made for some clue to their purpose. One relatively well preserved circle was cleared of all accumulated soil and debris and others were more briefly tested. In Square DD, a somewhat similar small enclosure, which been built against a high house-terrace wall, was completely excavated. In no instance could any positive information gained concerning the function of these enclosures. The stones were in each case footed on bedrock and ranged from about 60 cm to 1 m in height. Smaller

stones had evidently chinked the cracks between slabs as in the property walls. None of the small enclosures had an opening for entrance.

Reconnaissance was made through parts of Mayapán previously unvisited. Particular attention was given to locating and following lanes. All the lanes observed were formed by house property walls; nothing was noticed comparable to the long lanes in Square I. An effort was made to locate some kind of lane or roadway running between the Main Group and the large gate in the Great Wall in Square O. A reasonably straight route could be followed between the two points without crossing property walls, but no evidence of a road way or other formal route was detected.

In addition to investigations concerned directly with the property walls, explorations were made in order to determine the approximate extension of house structures outside the Great Wall. Trails were followed outward from the wall on all sides of the city, and the territory alongside the trails and in the many large milpas was examined. The number of house structures falls off sharply once the wall is crossed. East and west of the city, houses could be located in some number to about 0.5 km from the wall, but to the north and south, they seem to drop off a very short distance beyond the wall. As the density of settlement diminishes, houses are generally found only on the tops of the more prominent rocky knolls, these clearly being the preferred locations. It is of interest that even the most remote houses have enclosing property walls and that the enclosures are not significantly larger than those associated with houses in the more crowded parts of the city. Less than 0.5 km northeast of the sharp bend in the Great Wall in Square G, two large cenotes were discovered, both unfortunately inaccessible without a ladder. Below the wide opening in the roof of one cenote can be seen what appears to be a rectangular stone platform. House structures of Mayapán type are located near these cenotes.

Examination was also made of the territory along the two foot-trails leading from the northwest part of Mayapán to the village of Telchaquillo, a distance of slightly over 1 km. House ruins cease a short distance north of the Great Wall. At a point about halfway to Telchaquillo house ruins are again seen, and these appear to increase in concentration as one proceeds to the village, clearly suggesting that Telchaquillo was a separate center of settlement. Evidence of ancient construction is abundant, particularly west and south of the plaza of the modern village, and there are remains of large ceremonial structures near the plaza. Some of the house mounds on the outskirts of Telchaquillo have what appear to be property walls and, where surface features are visible, plans not unlike those of houses in Mayapán.

Early in the season a visit of several days was paid to Chichén Itzá, and in early May a trip was made to the Puuc region with Ruppert and A. L. Smith, one day apiece being spent at Uxmal, Kabah, and Sayil. The principal purpose in these visits was to look for evidence of a property wall pattern that could be compared with that at Mayapán.

At Chichén Itzá, trails were followed through the area west and southwest of the main ceremonial groups. The scarcity of trails and the density of vegetation prevented as complete coverage of the area as had been hoped for, but scattered for a considerable distance from the central part of Chichén Itzá are the remains of ruined structures ranging from small ceremonial groups to isolated platforms, usually on knolls, on which dwellings probably once stood. In one district, approximately 2 km west of the Castillo, a group of three small rectangular platforms, the largest 5 by 3 m, was found surrounded by a wall which both in construction and in plan seemed in every way similar to Mayapán property walls. Elsewhere in the same district, traces of similar walls were found which seemed likewise associated with house platforms, but these were infrequent. Most structures seen had no trace of a wall. In other areas, sections of occasional walls of boulders might be seen in the vicinity of what probably were house structures, but their rarity indicates that there was no such system of walls as at Mayapán. The one complete example found, however, is important, and is probably not unique.

At Kabah and Sayil, house structures were visited in areas near some of the large groups; at Uxmal an excursion was made for a kilometer or more west from the great ceremonial center. In general, houses at these sites appear to be restricted largely to knolls and heights of land. The low areas of deep soil are avoided. At Uxmal, where more territory was covered than at the other ruins, the impression was received of a very widely dispersed pattern of settlement. The only constructions seen that at all resembled property walls were a rough boulder wall at Sayil, running between two neighboring house terraces; and near the main aguada, or water hole, at Uxmal, a somewhat similar wall which formed an arc around the corner of a terrace bearing the ruin of small vaulted building. Neither wall can with certainty be stated to be ancient. It is clear that property walls are not a feature of Puuc houses.

In early February Bullard accompanied Dr. Gordon R. Willey, of Harvard University, and Dr. Linton Satterthwaite, Jr., of the University of Pennsylvania, on a ten-day reconnaissance in the Cayo District of British Honduras. Visits were made to the ruins of Benque Viejo, Baking Pot, and other ceremonial centers near El Cayo. Particular attention was given to locating house mounds. Recent agricultural clearings

on the terraces of the Belize River, about 5 km downstream from Baking Pot disclose a concentration of small mounds, presumably house mounds, which suggests a rather heavy population along the river at some distance from the ceremonial centers. Similar small mounds were observed sporadically in cleared fields alongside the Cayo-Belize highway from Cayo to Hog Style, near the beginning of a section of pine forest. Ruins are apparently not found in the pine forest area. On the outskirts of Cayo, examination was made of a cluster of small mounds in an open field about a kilometer from the ceremonial center of Cabal Pech. A test excavation was made in one mound. Part of a stone platform was uncovered and sherd samples were obtained.

40.12.

TATIANA PROSKOURIAKOFF

Plan of the Main Group at Mayapán

YB 52:264–268, 1953

Although the map of Mayapán completed by Jones in 1951 includes a plan of the principal ceremonial group, it is drawn at too small a scale to show individual structures with the degree of detail that comparative architectural studies require. It was decided, therefore, to draw a larger map of the Main Group at a scale of 1 to 200, showing all the plan details that could be observed on the surface or obtained by superficial digging and including also the results of more intensive investigations carried on by other members of the staff. Because of the height of the constructions and their crowded arrangement, direct measurements were often difficult to obtain, and the project involved a resurvey of the entire group. Pollock assisted in this work by supervising the surface excavations to develop the plans of the buildings, which Proskouriakoff measured and plotted on the map.

Some minor constructions are now so ruined that without deep excavation it is impossible to reconstruct their plans. Most of the principal buildings yielded fairly complete information as to their general features, although in some case deep fall covers details of substructures and interior elements such as benches and shrines. A debris line was used to indicate obscured areas. Elevations were taken on observed elements, and at least one cross section was drawn of each building. The datum, on a rock outcrop at 155 S, 290 W, just

outside the north entrance to the court of the Castillo, is 2.1 m above the datum of Jones map (Jones 1952)

This season's work covered only the northern half of the main ceremonial center, and another season will be required before a complete summary of civic and ceremonial building plans of the group can be made. Certain typical plans and assemblages, nevertheless, are already evident. As is well known, the central and tallest structure at Mayapán is a temple resembling the Castillo of Chichén Itzá in all but its size, its roof construction, and the quality of its masonry. The assemblage of buildings around the Mayapán Castillo however, lacks the spaciousness of the Chichén Itzá arrangement and resembles more closely the building group around the principal temple at Tulúm. Outcrops of rock, rising above the level of the Castillo court, are incorporated in the substructures of buildings that almost completely enclose the court. Two colonnaded halls and several smaller buildings about the pyramid of the Castillo, obscuring its lower terraces. A number of platforms and walls in the court further crowd the composition, so that only the crowning temple, towering above the roofs of other buildings, could be seen from a distance.

Building plans frequently recall the architecture of the east coast of Yucatán. Colonnaded buildings are probably more prevalent at Mayapán than in any other Maya city. Unlike most so-called "colonnades" at Chichén Itzá, the colonnaded halls of Mayapán are independent buildings complete in themselves. Three type plans are shown in Figure 40.12.1. The bench along the rear and side walls and a central altar or shrine are typical, as is also the corresponding central stairway. Structure Q-97 is the only example that has a transverse room at each end. More often a colonnaded hall has only one transverse room; some have none. In certain cases, rectangular piers are used together with

Figure 40.12.1. Mayapán, Main Group, typical building plans, (rectified and partly restored).

columns. Structure Q-87, which has two interior piers and no end room, has a plan which is little more than an expansion of the plan of a three-doorway temple, such as Structure Q-88. This suggests some functional variation of the type.

One colonnaded hall was decorated with mask motifs apparently reassembled from some dismantled building of the late Puuc style. The columns of another carry decoration of human figures in high-relief stucco. No colonnaded hall was vaulted. In some cases, beam and mortar roofing was clearly indicated by the debris; elsewhere, very scant debris suggests thatch-roof,

construction. It may be significant that no stones could be identified, as column capitals. This recalls a building practice reported from the East coast, where false capitals of stucco were sometimes applied to columns.

About as numerous as colonnaded halls at Mayapán are small, one-room buildings we designate as “shrines” (Structure Q-98). It is not certain that this designation is correct for all the small single-room buildings found in the Main Group, but some that have comparatively thick walls for their size seem analogous to the east-coast shrines, although probably none at Mayapán was vaulted and we cannot now determine their height. Some of these shrines stand on independent small platforms containing interment cists; others are built on the substructures of larger buildings with which they seem to have been associated (Str. Q-152a, Q-72a). A stone statue found one shrine (Str. Q-69) confirms their assumed religious function.

Temples with triple doorways formed by two columns or two square piers also be considered typical of Mayapán, though they vary more than do the colonnaded halls and shrines (Strs. Q-58, Q-82, Q-88). A central shrine or two piers seem to be common but not indispensable features of the interior. These temples stand on high substructures which sometimes have a burial shaft descending from the upper level to bedrock. The analogy with the construction of the so-called *Osario* or High Priest's Grave at Chichén Itzá is particularly marked in the case of Structure Q-58 which has a pyramidal substructure. The roofing of these temples, as of most buildings at Mayapán, was probably a combination of wooden beams, stone slabs, and mortar.

There are only two large vaulted buildings in the Main Group. One holds a prominent position among buildings north of the Castillo court. Its plan, unfortunately, is obscure and can be elucidated only by excavation. The building now appears as a thick masonry mass placed off-center on its substructure. A vaulted passage runs through the center, and secondary additions indicate major alterations of the original plan.

Another vaulted building is the Caracol (Str. Q-152), described by Brasseur de Bourbourg and by Stephens, who saw it before the last remnant of the vault had collapsed. The Caracol is the largest of four round buildings at Mayapán, each of which is the sole example in its group. On its high platform are a small shrine, a broken, crudely sculptured monument, fragments of carved hieroglyphic stones, and a large dressed stone that may have been a plain stela.

It was evidently the custom to center a small shrine or open platform on an important stairway, a custom that is also conspicuous in late preconquest sites of highland Guatemala. Small constructions, however, also occur without apparent relation to larger build-

ings. Without excavation it is difficult to determine the character of the numerous small platforms. Some, like the shrine platforms, are known to contain interment cists. The plan of these platforms is usually rectangular, but in one excavation a round interment pit was encountered, and surface observations suggest several more. None of the platforms observed so far has the typical form of the “dance platforms” or “mausoleums” found at Chichén Itzá. The platform in front of the Castillo, which in its earlier phases had four stairways, is the closest analogy, but even this was modified in form in later times.

A number of mounds on or near the periphery of the Main Group can be classed as house mounds, since they are very much like structures found in residential sections of the city. The location of Structure Q-62 near Q-64 and of Structure Q-86 near Q-99 suggests that the houses were built to serve activities carried on in the colonnaded halls, but Structure Q-91, situated on an outcrop of rock within the Main Group, has no apparent relation to a ceremonial structure and seemingly had a property wall delineating it as an independent unit. Bullard's investigation of Structure Q-86 shows it to be of later construction than the colonnaded hall Q-99 to which it is attached, leaving open the possibility that house mounds in the Main Group represent a late encroachment of the residential section on the civic center.

So far we have little evidence bearing on the growth and development of the city plan. All constructions observed seem to belong to one cultural period and to represent a single technique of building. An earlier time, tentatively identified with the period of presumably late Puuc-style structures at Uxmal and Kabah, is represented by many re-used, dressed, and sculptured stones, but no continuity between these two phases has been established. The chronological relation between structures at Mayapán and those of the Toltec style at Chichén Itzá also remains in question, although present observations tend to confirm Andrews' conclusions of 1942 [Chapter 36.3]. It is clear that building practices at Mayapán form a distinct complex, drawing on various sources. Such features as the low plinth of colonnaded halls and of temples, the apron molding on some substructures, and transverse rooms at the ends of long buildings probably survive from the Classic period of Maya architecture. Serpent columns, the occasional use of a sloping zone at the base of a wall, and certain other details mark the influence of Toltec culture. By and large however, similarities to the Toltec, phase of Chichén Itzá architecture are less numerous than analogies with east-coast practices. Particularly striking is the absence of certain building types, such as the ballcourt, the sweat bath, and the patio-gallery complex. The preponderance of colon-

naded halls may be viewed as an extension of a trend observed at Chichén Itzá, but the building of numerous independent shrines implies an emphasis on a religious practice that distinguishes Mayapán and the East Coast sites from other known Maya cities and probably indicates a profound cultural change of more than local significance.

40.13.

EDWIN M. SHOOK

Excavations at Mayapán

YB 52:268–272, 1953

Approximately half the 1953 field season was devoted to excavations of remains of buildings erected primarily for civic and religious purposes, and half the season to study of the material culture recovered from that work and, from the excavations of Adams, Bullard, Pollock, and Strömsvik.

The investigation of the twin temples, Structure T-70, near Cenote X-Coton and Gate T in the extreme southeastern sector of Mayapán was initiated in 1952 [Chapter 40.13], when, only the external features were exposed. During the current year the study of the edifice was completed. An exploratory trench was dug along the central east-west axis of each of the stairways and temples, following limestone bedrock. These trenches penetrated at least half the substructure, and shallower ones were continued to the rear wall of each temple. The trenching disclosed evidence in Structure T-70 of a relatively long sequence of building activity, covering, probably, the full span of occupation during the Mayapán period, and demonstrated the relation between the twin temples. The south one in its earliest stage and through three successive renovations stood alone as a single unit. The fifth remodeling of Structure T-70 was a major change, in which the builders extended the substructural platform northward in order to accommodate the single-chambered north temple. Thereafter the twin temples underwent five more renovations before their final abandonment.

No caches or dedicatory offerings, burials, or burial cists were encountered the stairways or in the platform fill. A small masonry altar against the rear wall of the south temple did, however, contain caches of pottery vessels, jade, and shell beads. These offerings in the oldest and most often refurbished temple,

and the presence of severely burned floors below a surface layer of effigy incensarios and ashes, indicated, religious and ceremonial activity centered more around the south than the north temple.

The placement of two temples on a common platform, each having its individual balustraded stairway leading up from the plaza level to the summit of the same substructure, is an architectural practice unknown in Yucatán or elsewhere in the Maya area, with 4-single exception (El Chile), prior to the Mayapán period. It is a feature associated with fortified hill sites of the Late Postclassic or protohistoric period in the Guatemala highlands and with sites occupied during the Aztec regime in the highlands of Mexico. The one example of this type of structure identified in Mayapán was constructed well along in the period of occupation, as is shown by the fact that four phases of building activity had taken place prior to the conversion of Structure T-70 into a double temple unit.

Within Square Q on the Mayapán map stands the central and dominant feature of the site, the Castillo or Temple of Kukulcan (Fig. 23, Str. Q-162). The temple surmounts a high terraced pyramid with a wide, balustraded stairway on each of the four sides. Tightly clustered around the pyramid within a radius of 100 m from its base are approximately 100 ancient structures of diverse types. A systematic plan of field work calls for the thorough investigation of one or more examples of each type of building. The character of many of the specialized units may be determined by this study, and light cast on their functions in the last coalition government enjoyed by the Maya in northern Yucatán before the arrival of the Spaniards. The excavation of what today may appear to be no more than a rock pile frequently yields more than architectural data. Below, and sealed by the discouragingly thick mass of fallen debris, lie the bits of evidence that must be pieced together to obtain even a dim reflection of ancient life in Mayapán. Pottery and artifacts, and their disposition on the temple floors, in terrace corners, and at the foot of stairways, tell a story of the final activities carried on before the abandonment and disintegration of the buildings. The position of burials in shallow graves, cists, or shafts, the type and number of interments, whether cremations, sacrificed victims of religious rites, warriors slain in battle, or normal deaths, all provide knowledge of the habits of the Maya. The presence or absence of animal and bird bones, pottery and artifacts, charcoal and ashes also aids in outlining the picture. The disposition and contents of rubbish dumps provide information on the material culture and its chronological order.

The major field excavations of the past season were limited to the northern half of the concentrated group centering on the Castillo. The work was closely

coordinated, and many members of the staff participated in each excavation. The study of a single unit was often initiated by one of the staff, continued by another, and completed by a third person.

One type of temple supported by a high platform or pyramid was first investigated, as it seemed to bear resemblances to the *Osario* or High Priest's Grave in Chichén Itzá. Prior to excavation, Structure Q-58 (Fig. 23) showed a much eroded, steep-sided pyramid supporting the remnant of a temple with a double-columned doorway. Within the building a deep, circular burial shaft with the form of a tall-necked wine bottle penetrated the core of the pyramid from the temple floor. The burial shaft lay open, obviously having been looted in modern times, as heaps of human, animal, and bird bones surrounded the orifice and spilled down the back talus of the pyramid. Strömsvik cleared the remaining contents at the bottom of the shaft and recovered evidence of more than four child and adult skeletons (a few bones showed burning, though most were unburned), a variety of animal and bird bones, a jade bead, charcoal, ashes, and fragments of obsidian flake-blades, unworked shell, and pottery.

Shook excavated the temple and portions of the pyramid of Structure Q-58. There were at least two major and four minor rebuildings. The first major construction consisted of a terraced pyramid and temple. The latter subsequently was torn down and another erected on an enlarged pyramid, which completely encased the earlier one. The second pyramid, also terraced, had a stairway on the east side flanked by broad balustrades leading from the plaza level to the summit platform. The temple, set back toward the rear part of the platform, had a triple doorway formed by two serpent columns between the widely spaced jambs. A simple plinth one step higher elevated the temple above the summit platform of the pyramid. The temple proper consisted of a large chamber with a small shrine room placed against the center of the rear wall. In the middle of the main chamber and directly in front of the shrine doorway was the small round opening of the deep burial shaft. The shaft apparently was kept closed most of the time with a capstone, and opened during rites to insert the bodies of the newly sacrificed.

There were four minor renovations of the temple, as evidenced by the refloorings and the replastering and painting of the walls. The lime plaster floor surrounding the entrance of the burial shaft and on the frontal terrace was heavily burned. Also, remains of broken incensarios lay in the corners of the shrine room, on the floor of the main chamber, on the frontal terrace, and particularly at the base of the pyramid next to the stair wall.

An alignment of small low structures, Q-59, Q-59a, Q-59b, and Q-60, lay on the central east-west axis

of Structure Q-58. They were erected at different times on the plaza floor in front of the pyramid stairway. Each unit, except Structure Q-59, contained a burial cist with from one to three skeletons.

Structure Q-82 (Fig. 23), a temple similar in plan to, Structure Q-58, was next investigated. This unit, because of its better state of preservation, was more thoroughly excavated, then solidified and left exposed as an example of Mayapán architecture. It differed from Structure Q-58 in several details. There was no burial cist or shaft associated with the temple, nor did the doorway columns bear serpent ornamentation in stone. A very heavy deposit of broken effigy incensarios lay on the temple floor, more concentrated in the center of the temple before the shrine doorway than elsewhere. All together, we recovered over 8,000 pottery fragments from the surface of temple floors, benches and frontal terraces, and around the base of the substructure. A vast majority of the fragments represent incensarios.

Structure Q-95, the third of the double-columned doorway type to be excavated, differed in several respects from Structure Q-58 and Q-82. The stairway of the structure did not carry flanking balustrades as do most stairways in Mayapán. Also, the earliest plan of the temple consisted of a single long room without the usual one-step riser from the frontal terrace into the chamber and without the inner shrine room. The two doorway columns square instead of round, with no evidence of having simulated serpents. Structure Q-95 underwent many renovations involving major changes both in the substructure and in the temple. Again there was much evidence of copal burning in incensarios, but seemingly not to the extent practiced in Q-58 and Q-82.

A deep, circular burial shaft placed in front of the temple penetrated the substructure from the top floor to underlying bedrock. Strömsvik excavated this shaft, which had been almost filled in ancient times with over 40 skeletons of children, adolescents, and adults of both sexes, bones of animals and birds, charcoal, ashes, pottery fragments, and artifacts of metal, bone, shell, and stone. Below the shaft and sealed by a capstone was a cavity in the bedrock. This apparently natural pocket in the limestone had been enlarged and utilized as a midden and burial place, then sealed prior to the use of the burial shaft. Within the cave were the artificially deformed skulls of two young children and the complete skeletons of an elderly man and woman. The female's head was severely deformed. The bulk of the cave contents consisted of ashes and charcoal mingled with an extraordinary number animal and bird bones. Pottery vessels, sherds, and artifacts of bone, shell, and stone were also present in minor quantities.

The investigation of another type of structure occurring frequently in the Main Group began during

the 1953 season with the excavation of Structure Q-97 (Fig. 23) This is a long colonnaded building, or hall, easily identified without excavation because it is supported by a low substructural platform and has a much greater length in proportion to width than other buildings, and the surface debris shows numerous column drums. Landa speaks of long houses as living quarters for boys and unmarried men. These colonnaded halls best answer his brief description.

Structure Q-97 consists of a long rear wall, its length broken twice by a passage or doorway near each extremity, a long central chamber or gallery with two rows of columns paralleling the rear wall, and a transverse room at each end. A plinth, one step high, elevates the floor of the building above the front terrace, and a raised bench fills the rear half of the central gallery.

A broad stairway leads from the plaza to the front terrace of the building. This, stairway is interrupted in the center by a small shrine in which we recovered fragmentary remains of a modeled stucco figure seated on a low altar or bench against the center of the back wall. The figure, apparently human, faced the entrance.

Directly behind the shrine and on the front terrace stand a sculptured stone monument and a small tapering stone block. The block resembles the altar shown in wall-painting scenes at Chichén Itzá, where an individual, held by attendants, is stretched supine over the block, and a priest cuts out the heart with a knife.

Within the building, placed in the center against the rear wall, was a masonry altar elevated slightly above the bench. The face of the altar bore a lattice-pattern decoration modeled in stucco, and at each front corner stood a small human figure also excellently wrought in stucco. Though the upper parts of the figures were not intact, it is possible that they served as small Atlantean figures supporting the projecting upper part of the altar. Atlantean figures carved in stone are fairly common in Toltec-period buildings in Chichén Itzá, and often occupy a similar position supporting a table-like altar. The shrine, the altar sculptures, the stucco figures, and the presence of many fragments of effigy incensarios on the floor and bench of Structure Q-97 suggest that elaborate ceremonial activities took place in this building. This does not necessarily eliminate the use of colonnaded buildings as living quarters.

The, pottery from the excavations of the above-mentioned buildings and from the structures within the Main Group cleared by Adams, Bullard, Pollock, and Strömsvik was studied. Most of the digging extended from the surface to bedrock and resulted in the recovery of stratified material representative of the site's occupation during the Mayapán period. The pre-

liminary analysis of almost 70,000 sherds collected during the 1953 field season in or near ceremonial and civic buildings indicates the continuity of the dominant wares with only minor modifications of form and surface treatment from the beginning to the end of the Mayapán period. The changes in the most common ware, Mayapán Red, though slight, prove to have chronological value. The innovations in this ware appear to represent the normal evolution one might expect to have occurred over the several centuries Mayapán supposedly was occupied. Among the less common pottery wares are such as Black on Cream (Brainerd's Coarse Slate), which are present in the beginning of the Mayapán period but gradually diminish in percentage in later times. New pottery types appear at certain levels, and others are limited largely to the latest surface deposits. Fine Orange, an imported ware, persists throughout the Mayapán period though never in appreciable amounts. No Plumbate was identified in any of the 1953 excavations; nor were there noted pottery types current, in the Mexican highlands during the Mayapán period, despite suggestions of foreign influence in some of the architecture, sculpture, and artifact at Mayapán.

During most of the Mayapán period the changes in pottery and architecture are too indefinite to permit, as yet, the division of the period into smaller chronological units. Toward the end of the site's occupation there is evidence of a new element in the local culture. Effigy incensarios came into use in such quantities that their fragments, often retaining the burned and unburned copal, cover the floors of temples, shrines, and colonnaded halls. There seems to have been a mania for appeasing the gods through ceremonial burning of copal in large censers decorated with effigy figures welded on the exteriors.

40.14.

ROBERT M. ADAMS, JR.

Excavations at Mayapán

YB 52: 272–275, 1953

As a part of the first season of intensive digging at Mayapán, excavations were carried out in and around a number of small ceremonial structures in the Main Group. In connection with a larger effort to elucidate the nature and function of the ceremonial center within

the city, this work was undertaken, in part, to define classes among some of the smaller and less imposing structures; typicalness, in other words, was an important criterion in the selection of sites for excavation.

About three weeks at the beginning of the season were devoted to the excavation of a trench north of Structure Q-79 (160 S, 270 W, on the map of Mayapán, Jones 1952). This operation was initiated on a modest scale under the direction of R. E. Smith in order to determine the circumstances surrounding a concentration of broken incensario pottery uncovered during work on a road that passes near the structure. A partial superposition of three floors was with over, a meter of total deposit and some evidence of a seriation in pottery. Later work showed that these conditions were not unusual in the Main Group, but at the time of digging they were unique, and the trench was gradually extended to a length of about 10 m in a futile attempt to relate the features uncovered to one phase or another of construction of Q-79.

The great bulk of pottery lay above the uppermost floor, and a substantial majority of the sherds were of figurine incensarios. These apparently had been broken elsewhere and discarded here, for prolonged attempts at fitting together sherds from the same provenience resulted in the construction of not a single complete or nearly complete figurine or vessel. The practice of discarding quantities of pottery, ashes, and other refuse in the vicinity of ceremonial structures was common elsewhere in the Main Group during the terminal period of occupation, but stands in contrast to the absence of debris on earlier floors. In this trench, for example, the earlier floors were separated not by refuse but by well packed fill in which sherds occurred only sporadically.

A feature of considerable importance was a group of seven articulated adult skeletons found above the uppermost floor in the trench. They lay about 5 m north of the north wall of Structure Q-79 apparently flung down side by side with trunks directed northwest and southeast fortunately. No grave offerings were present and less than 30 cm of earth covered all the skeletons, but their pre-Columbian antiquity seems assured by the presence of three large, crudely chipped flint knives; two were found within the rib cases of two of the individuals, and a third blade rested against the pelvis of another.

In the absence of any trace whatever of a higher floor, it seems an inescapable conclusion that these individuals were not buried appreciably deeper than they were found, although why they were not more disturbed by scavenging animals is difficult to understand. Since the skeletons occurred so near the surface in an area of some ceremonial importance, it is tempting to assume that their deaths were connected in some

way with the abandonment of the site, but, again, the ubiquity of scavengers in the region tempers the likelihood of any such conclusion. Had the bodies merely been left on the surface, or hastily and shallowly buried immediately prior to the abandonment of the center of the city, it is difficult to believe that any articulated bones would have been found at all. Although death by violence can probably be assumed for all of them, it is not possible to relate that violence to a specific historical event. In fact, death as sacrificial victims remains at least as likely a possibility as death in warfare.

At least two, and probably three, shrines were excavated by Adams during the 1953 field season. Structure Q-69 flanks an apparent northern entrance to the court of the Castillo (160 S, 290 W); Q-71 stands near, but in no clear relation to, a western entrance (180 S, 325 W). In both of these the final architectural form was cleared of debris more or less completely, and each was trenched sufficiently to determine the major phases in, and manner of, its construction. Structure Q-90 stands alone, near the center of a court or plaza to the northeast (150 S, 210 W); its identification as a shrine is less certain, and it was excavated only to the extent necessary to reconstruct its plan.

Each of these structures consists of a small room on a low terrace platform. Although details vary considerably, the shrine never has more than one room and is reached by a single stairway and entered through a simple doorway without columns. The absence of fallen roof debris within the shrines suggests the use of thatch, although the shrine walls are of typical Mayapán masonry. Roughly shaped or unworked masonry, heavily coated with plaster, and dry rock fill characterize the substructures, although veneer stones of the Puuc style of Late Classic period architecture were re-used in the stairways, balustrades, and plinths. Quantities of pottery and other refuse, including a large proportion of incensario ware, are found within the shrines and thickly bedded in surface levels around the edges of the platforms. An integral part of each substructure is an ossuary cist, containing the remains of several individuals, child and adult, male and female. Grave goods are few and poor, and manner of burial is uncertain; some skeletons are at least partly articulated, but the available space is so limited that it must have been necessary for one body to decompose before another was inserted.

Several phases of construction are generally evident. The substructure of Q-69, for example, reached its final dimensions (6.5 m by 5.5 m) only after three enlargements of the original small, rectangular platform, and its inset stairway on the south was not the result of initial design, but the effect of later extensions of the platform around a previously existing stair. Each

of the enlargements was progressively lower than its predecessor, so that the shrine finally rested on the summit of a small stepped platform. The standing human figures carved in stone and about natural size, were associated with it. Two had tenons for attachment to a wall or corner. These were broken and so badly scattered that their original positions remain problematical. The third figure seems quite certainly to have stood inside the shrine.

Structure Q-90 also consists of an original platform, which was subsequently enlarged. No definite trace remains of, the existence of a shrine on top of this slightly smaller structure (5 m by 4.8 m), but debris above the floor is most easily interpreted as the fallen masonry of walls. Here, too, the enlargement, was lower than the inner building platform and abutted the sides of the stairway, but fragments of associated statuary were not found in the limited exposures made.

Structure Q-71 on the other hand, was, built as unit (6.7 m by 5.8 m) and never enlarged, although it later was heightened slightly by the addition of a plinth. The outer wall of its substructure, above a few courses of rough block and slab masonry, is composed of two two-member moldings separated by a plain-narrow band, all of well cut and probably re-used veneer stones. On the north side a panel, which may have contained stucco figures, is inset in the moldings. Stucco figures occur on a front platform, below the stairs on the West, where they were built up around stalactites, presumably from the nearby cenote, into at least four free-standing statues. The shrine as a whole faces toward an imposing colonnaded hall on which it is imperfectly centered. Some apparently similar structures, not yet excavated, seem quite definitely to have been built to face such halls, but others, like Q-69 and Q-90, are independent of any larger complex. The question of different ceremonial functions for one basic building plan is one that can be answered at all, only by further excavation.

Structure Q-77, a low platform about 7.5 m square lying just north of the main (north) stairway of the Castillo (160 S, 280 W), was at first thought possibly to be related to, shrines in structure and function, but on excavation it turned out to be different in a number of important respects. The structure grew in stature as digging progressed, for it was founded on the underlying bedrock, and subsequent refloorings had raised the level of the surrounding court to more than half the platform's original 2 m height. In all, 12 successive floorings of the court were distinguishable around the side of the platform, including three in which the level was first uniformly raised with a continuous blanket of dry rock fill; furthermore the uppermost, floor in this sequence was followed for about 12 m to the north stairway of the Castillo, where five still higher patches

of reflooring were observable. This unmistakable evidence of continuity of occupation in the center of the main ceremonial group for a considerable period was welcome as it was unexpected.

Three phases were discernible in construction Of Q-77. In the earliest, the platform was ascended by stairs on all four sides and gave no indication of having supported a superstructure. The general similarity of its plan to that of the "dance platforms" at Chichén Itzá is unmistakable. It is preserved to its full height only on the north, and here Mayapán masonry in the lower courses gives way near the top to a narrow projecting molding and better-finished veneer stones resembling those used in the Puuc style of architecture; such stones also occur in the balustrades and stairways. After enough time had elapsed for several refloorings of the court, the north stairway was torn out, although one of its balustrades was incorporated in the projecting platform that was built to enclose the former area of the stair. This renovation, which may have included the erection of a small shrine on the new platform extension, effectively oriented the structure to face the Castillo and may be connected with some building activity on the latter. In a final minor alteration after the latest court reflooring, one corner formed between the platform and its extension was filled and eliminated.

Also extending to bedrock in the court of the Castillo was Structure Q-84, an apparently unique circular platform of crude, plastered Mayapán masonry, which was completely excavated. This structure does not appear on the Mayapán map, for successive floorings finally brought the court surface almost to the level of its top, and it was detected only during the more detailed examination of the ceremonial group that followed the preparation of the map. It is roughly 13 m in diameter and lies about 15 m east of Structure Q-77.

A number of large stone monuments, including a badly weathered serpent head, are at present on the surface of, or near, this structure, suggesting the possibility that it may have served as a monument platform, but no definite proof of this was found in the excavation. A cache of two tripod bowls and several very large flint and obsidian chipped knives may have been placed originally at the base of one of the monuments, but, if so, later movement of the stone has obscured the fact. If the platform did serve as a foundation for monuments, these must have stood open to the weather or have been sheltered at best by pole and thatch, for the total absence of debris above the level of the platform floor makes the former existence of a stone superstructure virtually impossible.

In its first phase of construction, the platform was 1 m or more above floor level and only 5 m in diameter.

It was subsequently enlarged at least five times, so that, in its excavated form its successive walls form a series of very irregular, roughly concentric circles, each of which was filled with rubble at the time of enlargement. As the court level was raised frequently during this process, the platform became relatively lower as it increased in size; and very late renovations along its southern edge, which are not very well understood because of their shallowness, may drastically have altered its previously circular shape. Crude and asymmetrical stairways without balustrades appear on the east and west in the second and later enlargements; if the earlier platforms were ascended by stairs, these were removed before the later enclosing walls were built. A thick-walled cist, about 2 m in inside diameter, was sunk to bedrock alongside the platform and near one stairway after the third enlargement had been completed and plastered. It was found to contain only a few fragmentary skeletal remains and no grave goods. The cist was incorporated within the structure by the fourth and later enlargements.

This work discloses, in sum, the existence and the character of some shrines, similar to one another in architectural design, and at least two kinds of ceremonial platform at Mayapán. At the same time, the breadth of variation found in both basic design and detail would indicate that further work on a number of similarly unimpressive examples of ceremonial architecture is necessary before the place of these structures in the archaeological remains of the site's ritual life may be thought to have been probed at all adequately. The features of the shrines as a group are perhaps clearest, but other functional or stylistic categories of small structures in the Main Group may not even be recognized yet.

40.15.

GUSTAV STRÖMSVIK

Exploration, Excavation and Reconstruction in Mayapán and Vicinity

YB 52:276–279, 1953

It was planned that early in September 1952 the exploration of ruins in the neighborhood of Mayapán would be initiated. This was prevented the torrential rains that continued long beyond the usual end of the wet

season in Yucatán. It was not until early November that two ruins to the south of Mayapán, Yacman and Xmulenscacau, which had previously been marked for closer investigation, could be visited.

The Yacman ruins had previously been visited by R. H. Thompson [Chapter 4.17], who had found no potsherds that could safely be dated later than the Classic period. Strömsvik collected sherds that, according to R. E. Smith, are evenly divided between the Mayapán and Puuc periods. A prismatic compass and tape survey was made of the dozen mounds that surround the cenote, and notes were taken on such architectural features as were visible.

The Xmulenscacau site is located about 200 m east of the Acanceh branch of the railroad from Mérida to Ticul, midway between Kilometers 62 and 63. These ruins were brought to our notice by Eugenio May, an experienced native employee, who had been commissioned a year earlier to explore the territory surrounding Mayapán. May reported sculptured stones and architectural columns, but on closer examination the ruins were found to consist mainly of platforms, at least eight of which were seen around the approximately 10m high pyramid that seems to be the center of the site. From the southeast corner of the pyramid runs a multi-chambered building, about 20 m long, doors facing north, with what may be a passageway through the center of the structure, and column-like, standing door jambs. It is probably these jambs that led May to report the presence of columns. Fragments of several broken metates were seen, but nothing that could be called sculpture. The ruins no doubt were wider spread, than could be observed at this time. Owing to the dense, impenetrable, and thorny underbrush, only a cursory survey could be made, but, enough was seen to warrant a closer examination when time permits. Surface sherds were all of Puuc types.

Across the rails, west of Xmulenscacau in the henequen plantation of the Hacienda Dzitincabchen, are also found ancient remains. About 2 km south of the beautiful Cenote Scoje, in a plantation called Zapata, are two pyramids of nearly the same size as the one seen at Xmulenscacau, but without a single worked stone. It is assumed that when the hacienda built all the face stone in the vicinity, used for building material.

Roughly a league from Hacienda Dzitincabchen, starting on the Sacalum road and turning north after about 1 km, weaving alternately through henequen fields and underbrush, one comes upon a cenote called Uxuchen. This cenote has a perennial water hole. It was said to have inscriptions carved on the rock walls. On examination this appeared to be so, but carvings were covered with fungus obscured. Later, during the latter part of March, Strömsvik, accompanied by Pol-

lock and Proskouriakoff, returned to study so-called inscriptions. On being scrubbed clean with fiber brushes and water, a band of pictographs emerged. These were sketched and photographed.

Excavations at Structure Q-58 Main Group at Mayapán were begun early in February. Strömsvik undertook the exploration of a deep vertical shaft that penetrates the pyramid substructure of this building from top to bottom. The present *comisario*, or mayor, of Telchaquillo, Sr. Felix Pat, relates that when he was a youngster, about 40 years ago, the owner of Hacienda Xcanchakan instructed Pat's father to dig out the shaft. Pat can remember nothing about what was found. At the bottom of the almost 1 m of debris that remained in the shaft, a solid, hard lime floor was met, and below this another. Under the last floor natural red soil, or *kancab*, was found in the irregularities of the underlying limestone bedrock. Pieces of the common Mayapán Red Ware were found in the *kancab*.

An attempt was made at tunneling under the stairway of Structure Q-58. This was abandoned as impracticable because of the amount of labor involved in solidifying the loose fill to ensure safe working conditions.

Guided by a depression in the surface of the terrace before the temple building of Structure Q-95, excavation disclosed another shaft similar to that in Structure Q-58. The rectangular upper passage was completely blocked with rocks. Below this the shaft became round and widened out to the form of a bottle, the space below the neck being filled with rubble mixed with earth. A few crumbly splinters of human bone were found, and sherds started to appear. Halfway down, the fill consisted mainly of human bones, mixed with ashes, potsherds, and rocks. Quantities of bones had been thrown in, disarticulated, helter-skelter, with masses of food refuse, such as animal and fish bones and ashes. A tiny gold flake was discovered and an even smaller copper fragment. A fair amount of potsherds also were found.

When bedrock was reached, a little over 4 m down, it was found that an oval stone had been fitted into a hole in the rock; when this was pried loose and lifted, an open space was revealed below. With a flashlight one could see a pottery vessel standing atop the ashlike debris about 0.5 m down. Also visible were the fragments of a child's skull sticking out of the ashes. In spite of high expectations, this small chultun-like cave contained little beyond a few potsherds, the fragmentary bones of two children that apparently were dismembered before being thrown in, and finally, at the bottom, the skeletons of two adults, a male and a female of advanced age, but without any recognizable grave offerings.

About 150 m east and a little south of Structure Q-162, the Castillo, lies Structure Q-127, a portal vault. It

is not associated with any existing wall, and its function as an entrance or exit is not clear. Since this is the only example of its kind known at Mayapán, it was thought advisable to examine it thoroughly. Part of the spring of the vault could be seen standing above the fallen debris. Like the Great Wall of Mayapán, it was constructed of crudely broken, unshaped or roughly shaped stone slabs laid without mortar. A narrow passage at the west connects with a portico, with one masonry pier and two columns, that faces east. The plan is essentially the same as that of the major gateways in the Great Wall (Shook 1952a). The western passageway of the portal undoubtedly was vaulted, as the first few stones above the spring could be seen. There is some question as to the manner in which the vault over the portico was constructed.

Separated by a hand's width from the east face of the northern half of Structure Q-127 is Structure Q-127a, a single-room temple with a columnar doorway facing east. The substructure, which carries a broad but simple molding at the top, shows some of the best masonry seen thus far at Mayapán, quite different from the typical masonry of the site. In spite of careful search clear-cut age difference, could be established between these two, widely different structures. A refuse or ceremonial dump, rich in pottery of the Mayapán period, was found in the narrow space between the two buildings.

Solidification and a small amount of reconstruction were undertaken in connection with several structures that had been excavated in the Main Group this past season. This work, which was in, the charge of Strömsvik, began early in April, and continued to the middle of June. From time to time, as need arose, Strömsvik consulted with Dr. Alberto Ruz L., of the Instituto Nacional de Antropología e Historia, in regard to methods and details of solidification and reconstruction.

Work began with Structure Q-82, a temple building. First the facing stones of the balustrades were carefully taken down and laid in proper order for replacing. All humus soil or loose earth was then removed to a depth of about 30 or 40 cm, both from the faces of the balustrades and from the staircase walls. These were then rebuilt with the removed stones, laid in the same order in rich lime mortar. The cracks between the stones were left open to be painted with cement at a later stage.

The balustrade at the south side was completely rebuilt with a vertical panel at the top. The vertical panel was to accommodate a serpent head with a deep tenon that was found at the bottom of the balustrade. As the lower stones of the balustrade were in place, precluding the possibility that the head had been tenoned into the masonry there, it was assumed that the

head had fallen from above and that a vertical panel at the top of the balustrade was the most likely original location. There are existing examples of such architectural design in the Maya area, and it was thought better to have the serpent head placed in the structure in a plausible manner than to have it lying loose on the ground.

The five existing steps of the stairway were reset in the manner described above except that here the humus and earth were removed to a greater depth before the fill was replaced, with rock and lime mortar, on which the steps were built. At the south side, abutting the rebuilt balustrade, the four missing upper steps, were partly reconstructed to indicate more fully character of the ancient stairway.

It was difficult to rebuild the substructural terraces to conform to the rude condition in which they were found, as native masons, in spite of having only elementary knowledge of masonry, could not bring themselves to build a wall crude as the ancients had made these. It should be pointed out, however, that the walls originally had been covered with a heavy coat of plaster.

The northeast corner of the temple building, which was missing structure was excavated, was duplicating comparable measurements of the south side of the building. A check against this location of the corner was provided by a single stone of the inner face of the north wall that remained in position. The two columns forming the triple entrance to the temple were reset to height they had when found, and another drum was replaced on the south column to give a better indication of the original appearance of the building. The walls and benches inside the temple were taken down and rebuilt to appear as nearly like the original as possible.

A few patches of floor were laid and were spotted with small stone chips to make the new floor clearly distinguishable from the old. Wherever the original fill of the structure protruded, as between the missing steps and the edge of the terrace floor it was capped with rocks laid in lime mortar and painted with cement, to look as much like the original fill as the materials used permitted.

At Structure Q-71, a shrine, the same procedure was followed. Except for the replacing of a part of the upper course of the cornice molding on the south side of the substructure and a few step stones, the structure was rebuilt to the closest possible likeness of what was uncovered. At the back or east side, the mid section of the substructural wall, carrying the original moldings, was left unexcavated; it remains covered with the debris accumulated since the building fell in ruin. The sides of the gateway from the court of the Castillo to the court on which Structure Q-71 faces were cleared and solidified to the height found.

In the solidification of the small platforms Q-59a, Q-59b, and Q-60, the same methods were followed as with Structures Q-82 and Q-71. These platforms are so small and low that, in spite of careful rebuilding and cement pointing, it is particularly important that they be kept free of the overwhelming vegetation if their solidification is to endure. This holds true, of course, for all reconstruction of buildings in these climates, however strongly built.

ROBERT E. SMITH

Pottery of Mayapán and Vicinity

YB 52:279–282, 1953

The first two months of the 1953 field season were spent investigating Cenote Ch'en Mul, located just east of Structure Q-162, the Castillo, in Square Q at Mayapán (Jones 1952). This cenote was selected because of its important central position in the main ceremonial group. Brainerd had dug two pottery test trenches there in 1942 and had found considerable depth of debris [Chapter 4.10].

Ch'en Mul is a jug-shaped cenote with a few banana trees growing on the floor in soil washed in through the rather large circular opening. The mouth is near the southern end of the cavern, the northern part being roofed by natural rock and extending north and northeast for more than 60 m. The cenote was used in ancient times as a source of water.

The main purpose of investigating this cenote was to obtain a good sample of pottery. A related project was to cut through the mound of dirt immediately below the cenote mouth. This mound, which was in the shape of a shallow crater, appeared to be of natural origin but, offered the possibility of proving to be in part artificial. It was also planned to find all possible water holes.

During the first week, with the assistance of R. M. Adams, a map was made of the cenote and pottery was removed by levels from pockets and depressions found close to the main (north) water hole. Although this pottery was predominantly of the Mayapán period, a few Puuc and Classic types were found. Of considerable interest was the appearance of Black on Cream Ware (Brainerd's Coarse Slate) in quantity, especially in the lower levels. Naturally, water jars were

preponderant, forming 95.2 percent of all sherds from this area.

The work on the mound of earth and debris below the mouth of the cenote was initiated by cutting a 1.5 m wide trench through the center from north to south, beginning at the south side of Brainerd's southernmost trench. Later, a column approximately 2 m square was cut from the west side of the trench close to the center of the crater. The column was about 2 m deep, arbitrarily separated into five strata roughly 40 cm each. Mayapán Red, Incensario, Black on Cream, and Puuc Wares were encountered at all levels; Fine Orange, in all but the lowest. A very few Puuc sherds appeared in the three upper strata, whereas in the two lower levels they formed considerable percentages (11.4 and 32.6 respectively).

A most important part of this central mound was the practically sterile red earth, locally known as *kancab*. It appeared below the surface soil, which varies in depth, from 50 to 84 cm, and, at a very early date, it probably composed most of the mound. The fact that a few small potsherds were encountered throughout this red earth may be ascribed to root channels, of which a number, of fair size, were noted. *Kancab* was, and still is, used to color pottery and in the construction of native house walls. It is presumed that large areas of gray and brown earth, stones, and pottery, apparently intrusive in the red earth, collected after the removal of *kancab* for the above-mentioned purposes.

Finally, a search was made for water holes other than the one mentioned above, which was about 2.5 m in diameter. One was located about 60 m from the banana grove, north 30 m, then east about 30 m. Another was found at some distance west of the mouth of the cenote, apparently under the Castillo. Each was smaller than the first. All the water holes were reached by trails still visible because of the sherds outlining them.

An exploratory pit, later extended into a 5.3 m trench, was sunk in the floor of Cenote X-Coton, resulting in what is probably the best stratigraphy so far encountered. This cut, Pit 3, situated about 9 m north of Cave 4 and 1 m west of Pit 2 (R. Smith, 1953, Fig. 1), was 1.5 m square by 1.8 m deep. Like the trench in Cenote Ch'en Mul, this pit-trench showed sections of *kancab*. The surface soil, varying from 50 to 80 cm in depth and composed of humus, roots, and some small stones, included some very large rocks, a few of which, probably fallen from the rim of the cenote, showed on the surface. Below were sections of sterile *kancab* and many large rocks, small stones, and sherds interspersed in a reddish-brown earth. Finally, at the bottom tremendous rock sections of the original cavern roof were encountered. A small man, was able to squeeze between some of these and, working in brownish sandy

soil apparently reaching to bedrock, obtained a small sample of largely Puuc and Classic ceramic types. This cut (pit and trench combined) was divided into six strata, which showed from top to bottom a steady decline in Mayapán-period pottery types and an equally steady increase in Puuc types.

The investigation of what apparently was an ancient *sascab*, or marl, quarry (370 S, 35 E), begun by Shepard in 1952 was continued. In the deepest part of the quarry Shepard had sunk a small pit about 70 cm deep, which actually marked the depth of the surface soil. This original pit was broadened and extended and call Pit 1. The material found strongly suggests that the location was a refuse dump, which is not surprising since house platforms surround the quarry. Pit 1 contained over 3,500 sherds, many flint chips, obsidian knife-blades, shell fragments, and animal bones, plus a shell ornament, worked bone, a flint point, and a mano. The pottery was preponderantly of the Mayapán period from top to bottom. The only significant change noted was the very definite decrease in effigy incensario sherds in the two lowest levels. No Black on Cream pottery was found.

Another pit was started in the southeastern part of the same quarry, but solid rock was encountered at a depth of approximately 40 cm. Ceramically, the Pit 2 material equates with that found in the surface soil of Pit 1.

A basin-shaped depression, probably the blocked entrance of a cenote, was investigated in Square L (450 N, 275 W). It measured roughly 16 by 24 m at the rim and had what appeared to be a subsidiary opening a few meters to the southeast. Four levels were cut in the main depression. The surface humus, a shallow stratum, contained virtually no pottery. The next three levels, composed of small stones and dirt, yielded only a little over 200 sherds, all belonging to the Mayapán period. At a depth of 1.7 m very large stones, closely packed, made further descent extremely difficult. The small pottery sample thus far obtained did not warrant further digging, and the project was abandoned.

In the main plaza of Telchaquillo, a village close to Mayapán, there is a sizable cenote with a large main water hole. The cenote is jug-shaped but has two mouths, one centrally placed, the other a ramp-like entrance from the west which terminates in crudely fashioned steps near the water. Another stairway, well constructed, was uncovered in the center of the cenote. There is also a well shaft cut through the roof of the cavern, presumably in colonial times, but no longer used. Brainerd in 1942 dug a pit in the southeast corner of the cenote, finding only post-conquest pottery [Chapter 4.10].

After the cenote was mapped, a pit almost 2 m square was sunk about 2 m northwest of Brainerd's.

Four 30 cm levels were cut. The surface level contained nothing but post-conquest red jars (some are brownish) and three glazed white or polychrome pieces. The next level included 16 Mayapán Red jar sherds Plus 2 Black on Cream fragments with 172 fragments of post-conquest red jars. The stratum below had a total of 558 sherds, of which eight were Mayapán Red. The bottom level was a small lot of 92 sherds, including 17 Mayapán Red and one from a Puuc Medium Slate jar. The pottery from these excavations that has been identified as Mayapán Red may conceivably be, with the exception of two rim sherds, of post-conquest period. At times body sherds of these red wares are all but indistinguishable, a slight difference in surface texture being the only identifying mark. Rim forms, however, are distinctive, and the two rim sherds mentioned are unquestionably Mayapán Red.

A second but much smaller water hole was found due west of Pit 2, and a small nearby pocket containing dirt and potsherds was excavated. This lot of 45 sherds had only two post-conquest examples; the rest included two Mayapán Red, 28 Black on Cream, three Puuc, seven Early Classic, and three unidentified fragments. Pit 3 was dug under and north of the crude north stairway. It had two strata, the upper having a preponderance of post-conquest red jar fragments plus a few Mayapán Red, Black on Cream, and Puuc sherds, the lower including fewer post-conquest jar sherds and a greater proportion of the earlier types.

The pottery of Mayapán is abundant, almost 150,000 sherds having been collected thus far. It is simple but for the effigy censers, which are elaborately adorned and full of symbolism. As might be expected, a preponderant proportion of the pottery (over 80 percent) seems to be representative of the principal architectural period of the site, the so-called Mayapán period. The ceramics of this period from the main ceremonial center are discussed by Shook (Chapter 40.13). The trends noted there are essentially the same as those seen in the pottery from elsewhere in Mayapán. Differences worth noting are that effigy censers occur in considerably greater proportion in the ceremonial center, whereas Black on Cream Ware (Coarse Slate) is virtually absent in house mounds, although, the number of these presumably domiciliary structures so far excavated is not sufficient to be at all representative of the site as a whole.

As was noted in last year's report [Chapter 1.41], the only other major ceramic period at Mayapán is that of the Puuc (3.4 percent). Parenthetically, it should be noted that 13 percent of all pottery from the site is unidentified because of its fragmentary nature or weathered condition. Often associated with the Puuc pottery is a small amount of polychrome, some of it Petén-like, some of it local to the peninsula, seemingly,

of both Early and Late Classic periods. Most of this Pottery, Puuc and Classic polychrome, comes from excavations in cenotes.

A few figurines (77) occur at Mayapán, and there are trace amounts of special forms (miniature vessels, masks) and rare wares (Thin Slate, Fine Gray, Tohil Plumbate). Also in trace amounts are Formative-period sherds.

The important trade ware at Mayapán is Fine Orange (545 sherds). Mostly it seems to be of a late type associated with the Mayapán period, although rare examples of X and Z types occur.

The ceramic problem concerning the Toltec period at Mayapán, mentioned in last year's report, remains unsolved. It is likely, moreover, that only further work at Chichén Itzá can provide the answer. With the exception of two sherds of Tohil Plumbate and a handful of X Fine Orange, no pottery has been found at Mayapán that can at present be assigned to the period in question. There is some reason to believe that the site was not occupied at that time. We cannot put aside the alternative, however, that the Toltec period, commonly thought to intervene between Classic Puuc times and the Mayapán period, may in fact have been coeval, or in part coeval, with either the Puuc or the Mayapán period. In such case the occupation of Mayapán might have been continuous from Classic to protohistoric, or even historic, times.

40.17.

TATIANA PROSKOURIAKOFF
Artifacts of Mayapán

YB 52:282–283, 1953

Although there was more excavation this season than in 1952, the number of catalogue entries (238) was about the same as last year (229). The increased number of objects from excavations was offset by greatly reduced surface collections. The material gathered this year is consequently more evenly divided among different classes of artifacts, and less weighted in, favor of stone tools, which survive exposure best. Among the 54 chipped flint implements recorded this year are five arrowheads, rarely found elsewhere in Yucatán. Notable, too, is a small (approx. 6 cm) roughly, triangular or hatch form with a working edge at the base. Most chipping at Mayapán is of indifferent quality,

but several finely chipped, large thin blades, came from a cache in the Main Group, and three knives or points, similar in form to the sacrificial knives of Chichén Itzá, were found with human skeletons near the surface.

Of the larger tools recorded, 36 were of limestone or chert and only eight of volcanic or other imported stone. Obsidian flake-blades were numerous. All these were recorded, but only a few outstanding pieces were included in the specimen catalogue. The catalogue also lists several obsidian cores, two “thumbnail” scrapers, and one particularly large, fine chipped blade found with similar blades of chert in the previously mentioned cache.

The jade collection from Mayapán is still meager. Twenty beads were recovered, only one of which is distinguished by its unusually large size (diameter 4 cm). The jade varies in quality and color, and many pieces are discolored by burning. Other objects of fine stone include four fragments of greenstone celts and a small (6.6 cm) head of dark igneous stone carved in the Olmec style. This is probably the most interesting piece in the Mayapán collection. It is carved in the manner of a “mask,” hollowed out in back and bearing two perforations on each side. The typical features of an Olmec face are depicted in very simple forms, lacking the delicate curvatures of the finer Olmec sculptures. It is hard to judge whether this piece survives from the Classic period of Olmec art or is a later imitation.

Artifacts of materials other than stone include fragments of sculptured stucco, bone awls and needles, perforated animal and human teeth, pottery spindle whorls, a pair of pottery earplugs (probably of Fine Orange paste), a copper bell, a tiny fragment of gold, and numerous ornaments of shell. A fragment of a shell ring of the type that has been called a “collar” is incised with hieroglyphs. The glyphs have ascending coefficients of 1, 2, 3, and 4 dots, suggesting a series of days of the *tzolkin*, or Maya day count, but although the glyphs look Maya, they cannot be identified with any known characters. If they are not merely an individual invention but represent a variant of Maya calligraphy or a system of writing yet unknown, it is hoped that more examples will be discovered.

40.18.

A. LEDYARD SMITH AND
KARL RUPPERT
Mayapán, Yucatán

YB 53:267–268, 1954

About two-thirds of the 1954 field season, January 16 to May, was spent in completing the square-by-square surface examination of the structures within the Great Wall of Mayapán or directly associated with the site. This survey, started in 1951, had occupied most of Ruppert’s and Smith’s time during the three preceding field seasons [Chapters 40.3, 40.5, and 40.10]. The remainder of the 1954 season was devoted to excavation at Mayapán and exploration at Chichén Itzá. Ruppert also investigated several small sites in the environs of Telchaquillo.

The survey of Squares Y, Z, and AA this year completed the surface examination (Jones 1952). During the season 813 structures were inspected, making a total of 4,140 examined and recorded on file cards since the beginning of the survey. This is naturally not the exact total number of structures at the site, for not only were there probably some that have been destroyed completely in the building of the many modern walls, but further excavation may bring other structures to light. The approximate number of buildings which from their remains can be said to have served as homes is 2,100. There are, however, many platforms with no traces of superstructures that may well have supported buildings, constructed entirely of perishable materials, which possibly served as dwellings. These are often found associated with house groups and may, of course, have been kitchens or have had some other function. Altar shrines also are often associated with family groups. Although no new types of dwelling were found this season, some refinements or amendments were noted in the general categories established during previous years.

As has been the custom in past seasons, the presence of Puuc-type stones in buildings was noted, and the location of metates was indicated. Almost all metates are of the legless, grooved kind. Several fragments of metates with legs were found, however, and there was one complete example, including the mano. The metates without legs are of limestone; the kind with legs are of tufa, a material not indigenous to Yucatán. An unusual specimen recovered is one with legs and grooved.

During the first part of the season several days were spent in a small group of mounds in Square A,

about 250 m outside the city wall. The group, which rests on a slight rise, is surrounded by a stone wall averaging about 1 m high and 1.4 m thick with an entrance in its north end. Several pits were sunk in one of the structures, exposing a tomb containing two skeletons. The pottery recovered all proved to be of the Mayapán Period.

Structure Q-62 was chosen for complete excavation, as it was situated in the main ceremonial group and was a good example of an average dwelling. It was also hoped that its relationship in time could be established with a nearby colonnaded hall, Structure Q-64. Unfortunately this could not be done. The dwelling consists of a front area with three benches and a back part divided into three rooms: the central, room having a bench along its back wall. Passageways lead from the front to the rooms in the back. The west rear room has a doorway opening out of its west side. The lower portion of the walls was made of stone and probably never rose in more than 50 cm. The upper part of the walls and the roof undoubtedly were of perishable materials. Two burials were found associated with Structure Q-62. One, containing three adult skeletons and three human effigy incense burners, was in front of the structure in line with the central passageway; another was under the central bench. The latter burial held three child skeletons and a collection of pottery whistles representing human figures, animals, and birds. After this building was excavated and mapped, the masonry walls and plastered floors were solidified by Strömsvik.

Other excavations were carried on in various structures in Squares Z and AA where the possibility of finding burials was indicated by depressions or where part of a buried vault was showing. In several instances burials were exposed; in others, nicely constructed stone vaults were found with no skeletal remains. One of the best built vaults was under the west bench of a large dwelling with stone columns (Structure Z-4-b). Here the vault, which was partially corbelled, was entered through a narrow passageway leading from the terrace at the west end of the building. In this case the vault was filled to the spring of the arch with earth, stone, and pottery, and the passageway was completely filled.

During the three years in which excavations have been carried on in house-type structures, pits have been dug in every location associated with them. Burials were found in benches, passageways, front and back rooms, and terraces. There does not seem to have been any definite rule about burying the dead, for not only did the location vary, but also the method. Sometimes the remains were placed in well, built tombs, sometimes in simple cists through the floors of structures. There is no doubt that in most cases the well made

vaults were constructed at the time building the house, with the idea of eventual use for burial purposes.

Although little, grave furniture was found with burials this season, some interesting finds were made, including several copper rings, three still on one of the phalanges of a skeleton, and a pair of copper tweezers. The recovery of parts of pottery figurines with articulated arms and legs was also interesting.

Sherds of the Mayapán Period were present in all the samples recovered by Ruppert and Smith. In the more elaborate house types excavated by Thompson and Proskouriakoff there was a small percentage of Black on Cream Ware which was not represented in pottery from dwellings outside the proximity of the main ceremonial group. It is possible that the people living in the more pretentious dwellings used this type of pottery. Excavation should throw more light on this subject.

During the season four sites, Chun Uc, Chan Pixya, Haol, and Jaba, within easy walking distance of Telchaquillo were visited by Ruppert. They are small ruins located near cenotes and all have house types like those found at Mayapán.

40.19.

TATIANA PROSKOURIAKOFF

Mapping and Excavation at Mayapán

YB 53:268–271, 1954

The map of the Main Group begun last season was completed this year with the assistance of Strömsvik, who performed all the excavations necessary to uncover building plans. The area covered now includes about 130 structures.

The extension of the map has not modified substantially the architectural picture as it was outlined in 1953 [Chapter 40.12]. The colonnaded hall remains the dominant building type at Mayapán, with 22 examples mapped, of which the larger and the more elaborate tend to occur in the southern half of the Main Group. Residential use of these buildings is suggested in a number of cases by the close association of dwelling-type structures, which seem to be built to provide household service for the halls. This greatly enhances the possibility that the colonnaded hall of Mayapán is a counterpart of the Mexican *Telpuchcalli* (bachelors' house) or of the *Calmecac* (monastery). Almost every

hall has a central ceremonial feature, such as a niche or an altar, interrupting the rear bench. Often this central feature was later enclosed in a small shrine; sometimes there is a shrine in the center of the front stairway. In at least nine instances, a platform, shrine, or small temple stands in front, facing the colonnade.

Temple architecture at Mayapán reveals two types of plan and a number of variations. The Castillo, the partially vaulted Structure Q-80, and Structure Q-95 are prominent temples, each of different design. Structures Q-152 and Q-214 both are round in plan, but differ in size, interior arrangement, and roof construction. A more uniform group is formed by Structures Q-58, Q-143, Q-159, and Q-218, all pyramid temples with grotesque columns probably ending in serpent tails. These temples answer the description of the *Cu* or *Teupan* of Mexico. Their number at Mayapán recalls the traditional fourfold division of Mexican towns as well as the four "divisions" or lineages mentioned in Maya history. In front of each are a shrine and platforms centered on the axis of the façade. The second type of temple plan is characterized by a lower substructure, two plain columns in the doorway, and two interior piers. Structures Q-82, Q-55, Q-88, Q-153, and Q-202, representing this type, are less prominently placed than the pyramid temples and do not have subsidiary structures.

The 36 temples and colonnaded halls, together with Structures Q-42a, Q-158, and Q-163a, the nature of which is not clear from the visible remains, can be considered the major civic and religious building of the central group. There are numerous minor buildings that yield less readily to classification. What we call a shrine is typically a one-room building raised on a small platform, facing and centered on a temple or colonnaded hall. Identical small buildings, however, occur independently; on the other hand, subsidiary structures have every degree of elaboration and some are better described as small temples. A general class of subsidiary and minor buildings of one or two rooms would include 23 structures of known plan. Five of these are subsidiary temples or elaborate shrines (Q-141, Q-148, Q-149, Q-155, and Q-201); six are smaller shrines (Q-69, Q-71, Q-89, Q-90, Q-98 and Q-216); 12 are one-room buildings of doubtful function, some on independent platforms and others in some way attached to larger structures. Structures Q-61a, Q-82a, and Q-157a are tiny constructions even smaller than the typical shrine, built possibly to house a single idol. The interior of the largest is hardly more than a meter square.

In addition, there are 21 platforms of various kinds, some of which may have supported small superstructures with plans not now apparent. Eight of these are centered on larger buildings, and one, Structure Q-84,

may have served as a platform for monuments. Ten other minor structures are too fragmentary to identify, and two sizable platforms, Q-152c and Q-160, have only traces of masonry walls and very little debris to indicate a superstructure. They may have served as foundations for perishable buildings, or perhaps they were not in use at the time of the city's abandonment. Sixteen dwelling type houses and platforms associated with them complete the total of 114 structures in the ceremonial group. Sixteen others mapped belong to adjacent house groups. The area covered is about 200 by 300 m. This is a very crowded arrangement as compared with plans of earlier ceremonial centers, which are designed more spaciouly and on a larger scale. It undoubtedly results in part from the space limitations set by the city wall and in part from a decentralized ritual organization-serving a multiplicity of cults.

Thompson's excavations in Structure Q-208, a dwelling-type building, uncovered some fine ritual objects, and architecture that rivals in scale and quality that of many public buildings. The question arises whether such structures were homes of the aristocracy, or if they were, community ritual centers on the order of the Mexican *calpulli*. There are several imposing groups of such houses in the immediate vicinity of the ceremonial center that were not covered in the house survey [Chapter 40.10] and are indicated on the map of the site with conventional mound symbols. One such group was cleared of bush this season, and minor excavations were made to clarify its plan.

The group is about 200 m east of the Castillo and is one of two that are almost identical in plan. It is built on a natural rise in ground, terraced on all sides to form a raised court. Three houses (R-85, R-86, and R-87) set on high foundations, enclose the court on the north, west, and south; at the southwest corner steps lead down to a vaulted passage which provides entrance and exit from the court under one of the houses. The building plans are typical of the Mayapán dwelling, with an open front gallery and a range of rooms in back. The galleries, however, are unusually wide (that of Structure R-87 exceeds 4 m), and the heavy columns are widely spaced. What masonry can be seen is superior to any observed in the Main Group.

On the east side of the court, a less solidly built house, Structure R-88, stands directly on court level. In front of it are two small shrines. One of these, Structure R-90, facing west and centered on Structure R-86, is built on an extension of an earlier terrace. The other, Structure R-89, facing in the opposite direction, is built against this terrace at a lower level, and is approached by a short flight of steps leading into a small areaway. Two "column" altars with carved moldings and a cylindrical stone were lying in the court, apparently moved from their original positions.

It was obvious that someone had previously excavated in this group. A pit had been dug destroying the head of the stairway leading into the vaulted passage. Another was noted in the doorway of the southeast room of Structure R-88, and third in front of the shrine R-90, where one, of the "column" altars probably stood. In clearing this pit, we found a small cache bowl representing a turtle and containing a fine obsidian flake-blade in place just under the surface of the court. A fourth early excavation was a trench through the northeast room of Structure R-85, breaking the medial wall and passing into the bench of the front gallery. It is inconceivable that this was done by an experienced archaeologist or by the departing Maya. The holes were patently made in search of caches and objects of value, but there is little hope of learning when and under what circumstances.

The lower shrine, Structure R-89, had also been entered; there was a pit inside it against the rear wall, where normally an altar would be placed. Afterward, the areaway had been filled with stones, many of which are carved in the Puuc style. Sizable trees had grown up in the areaway since it was filled, but the growth of the Yucatán bush is so rapid that this hint of the age of the excavations eliminates only the past few years.

Unlike most buildings at Mayapán, R-89 still retains its roof intact. The construction is something in the nature of a very, crude vault, formed by a corbel of several layers of irregular slabs projecting from the three free-standing walls, and supporting one very large and one smaller capstone. The door is spanned by a stone lintel, and the upper façade is a single three-member molding probably interrupted by a central decorative feature. There are traces of secondary construction on the roof. In front of the shrine are two stone rings set into the floor of the areaway, which is drained by a small rectangular opening in the floor near the northeast corner. The areaway is secondary to the shrine, which in turn appears to be later than the terrace against which it is built. There are clearly several building periods which involve other structures in the group, but it was not possible this year to investigate the sequence in detail.

Minor investigations included the removal of debris from the main stairway leading to the court at its northeast corner, and from some of the rooms of Structure R-88, which has a rather unusual plan that required clarification. Partial clearing of the stairways to Structures R-86 and R-87 and to the vaulted passageway showed at least two sequent building operations, and a buried terrace in the middle of the court suggested a radically different arrangement of the group at an earlier stage. It is hoped that more excavation can be carried on in the group, for it shows prom-

ise of yielding a determinable sequence of constructions containing ritual artifacts of high quality.

EDWIN M. SHOOK

Excavations in Mayapán

YB 53:271–273, 1954

The 1954 field season witnessed the continuation of a program to investigate systematically one or more examples of each type of building found within the principal ceremonial group at Mayapán. This study, initiated in 1953, engaged the efforts of most of the field staff and neared completion by the end of the present season. As part of the general plan of investigation, Shook excavated the Castillo (Structure Q-162) and a round temple (Structure Q-214). He also made stratigraphic tests around these units for data bearing on the growth of Mayapán and the evolution of ceramics during the major occupation of the site. The pottery from these excavations was studied in conjunction with that recovered by Irving, Pollock, P. E. Smith, and Winters from other ceremonial buildings.

The most prominent architectural feature at Mayapán is the so-called Castillo or Temple of Kukulcan. It is a terraced pyramid, approximately 15 m in height, with a balustraded stairway on each of its four sides. Tightly clustered around the pyramid are the numerous lesser temples, colonnaded buildings, shrines, houses, and platforms which form the civic and religious center of the ancient city. Several of these units, built after the Castillo pyramid, abut or overlie its lower terraces.

The study of Structure Q-162 established the existence of an earlier, buried pyramid entirely enclosed by a later one. The inner unit, representing one of the first temples erected in the Mayapán Period, apparently differed only in size from the final structure. Both had plain, battered terrace walls constructed of the typical Mayapán block and slab masonry. Though we probed to a depth of 2 m through the dry rock fill below the top floor of the later temple, we did not encounter an earlier superstructure. It appeared likely that the building had been razed by the builders of the second temple, as was the case in Structure Q-58 [Chapter 40.13].

Our excavations at the north and west base of the Castillo disclosed that only two successive court floors

had joined the earlier pyramid, whereas at least nine floors, each representing renewed building activity, turned up to the stairway of the outer unit. Also, no less than 17 successive lime floors were found in the late temple on the summit of the pyramid. These numerous remodelings and the pottery sealed below the primary floor indicate that the construction of the later Castillo took place quite early in the Mayapán Period.

The temple, similar in plan to the Castillo in Chichén Itzá, has its principal entrance on the north side. Here a triple entrance formed by serpent columns leads to a transverse chamber. Access to the central sanctuary is gained through a single doorway from this northern chamber. Surrounding the east, south, and west sides of the inner sanctuary, but with no interior means of communication with that room, it is a narrow continuous gallery with a single exterior doorway centered on each of the pyramid stairways. The masonry walls of the temple supported a flat beam and mortar roof. The roof types was evident from the composition and amount of fallen debris in the rooms, the absence of stone adequate for vaulting and particularly from the width of the inner sanctuary. This chamber originally had had a masonry altar against the center of the south wall, opposite the doorway. Before the collapse of the temple roof, which buried the floor and lower walls to a depth of 1.3 m, the masonry altar had been torn out and a hole dug 50 cm below it. We assume this destruction was done, at the time Mayapán was abandoned, by looters in search of offerings known to be contained in the altar. Why they took the trouble of refilling the hole with the debris, from their digging is not clear. Among this disturbed material we recovered shell beads and ornaments, obsidian flake-blades, chipped flint implements and many pottery fragments from small vessels and censers. The pottery objects may, have been accidentally broken, and the small artifacts of shell and stone overlooked or not valued by the ancient looters.

Most of the 17 floors representing different refurbishings of the temple bore evidence of much burning. The heaviest concentration of burning took place on the north-south axis of the building from the front terrace to the altar in the sanctuary. Despite the blackened areas and lenses of copal incense between certain floors, there were relatively few censer fragments on the temple floor or at the foot of the north stairway. Several other temples (Structures Q-58 and Q-82, for example), colonnaded buildings (Structures Q-81, Q-97, Q-151), and shrines (Structures Q-69, Q-71, Q-90) were found to be littered with broken censers. Perhaps the Castillo, being the most important temple of the city, was carefully tended and kept clean, whereas slovenliness was permitted in less sacred buildings.

No burial shaft was found in the Castillo. A tapered stone block of a type associated with sacrifice was, however lying at the base of the north stairway and suggests that, sacrifice may have been made before the temple.

The next building investigated was a round temple, Structure Q-214, located about 100 m south of the Castillo. It occupies the central position on the west side a small plaza and faces east toward a temple with serpent columns (Structure Q-218) on the opposite side of the plaza. Structure Q-214 consists of a circular out wall with the interior space divided in half by a partition wall. A single doorway provides access to the front room; another in the partition wall, to the rear chamber. These rooms, small and semicircular in plan, apparently had been vaulted. A burned area 50 cm in diameter on the floor at the center of the rear chamber and opposite the doorway indicated some ceremonial use of the temple. Also, many fragments of human-effigy censers lay on the floor near the back wall, and quantities of such pieces came from around the base of the platform supporting the temple.

The 2 m high platform had square corners on the east or plaza side; on the back or west side each corner was rounded stairway with plain flanking balustrades led from the plaza level to the broad terrace in front of the temple. Originally, the flight of steps was uninterrupted, but at some time after the primary construction, the lower central part of the stairway had been cut into and a miniature shrine room erected there. This tiny roofed chamber housed a stone idol depicting a bare-breasted seated female. The statue sat against the back wall of the shrine facing the doorway. Below the sculpture we discovered an offering that consisted of several jade and shell beads in a small effigy vessel. The female figure, the first of its type to be found in Mayapán, may be the important Maya goddess Ix Chel, and thus may throw a new light on the function of the round temple.

Stratigraphic excavations were made in a deep midden of temple and household rubbish off the southwest corner of Structure Q-24. These produced a sample of sequent materials for the latter half of the site's occupation.

Of more value in establishing ceramic chronology from the beginning of the Mayapán Period were the excavations between Structure Q-77 and the north stairway of the Castillo. Here a vertical sequence of 13 plaza floors from bedrock to the present-day surface spanned the life of the site during the Mayapán Period. Of the oldest material, in the soil overlying bedrock and sealed by the earliest constructions, 94 percent was of Mayapán Period types, the remainder being weathered fragments of Puuc and other pre-Mayapán types. In other words, the small amounts of earlier

material in the old surface soil indicate habitation in the immediate vicinity prior to the Mayapán Period occupation, but there was no evidence of any construction's having existed in the area tested until the establishment of the political capital of Mayapán.

The major pottery types of the Mayapán Period were current in the oldest level and, except for Black on Cream, continued with minor changes throughout the sequence of floors, or for that matter until the abandonment of the site. Pottery censers are present from the beginning, but the human effigy hourglass type does not appear before the latest constructional activities and is most common on the surface floors, a condition true of every type of structure so far investigated in Mayapán.

40.21.

PHILIP E. SMITH

Excavations in Ceremonial Structures at Mayapán

YB 53: 273–276, 1954

Virtually the entire season was devoted to the excavation of three ceremonial structures in a relatively concentrated area of the Main Group. The most important of the three was a temple, Structure Q-153, adjoining Cenote Ch'en Mul, which is at the eastern base of the Castillo. Following the excavation of this temple and its adjacent constructions around the mouth of the cenote, two smaller, single-room buildings (shrines or subsidiary temples) about 30 m east of the cenote were investigated. The work in general was a continuation of the effort begun last year to determine by intensive digging the nature of certain ceremonial structures and their functions in the life of the Main Group.

Owing to the obviously significant ritual position of Cenote Ch'en Mul in the main ceremonial center of Mayapán, it appeared desirable to try to determine the nature of the adjoining temple and whether it would give any indication that a cenote cult had been fashionable at Mayapán as at Chichén Itzá. A Spanish missionary who visited Mayapán less than 50 years after the conquest of Yucatán reported that according to local tradition victims were thrown into this sink after being sacrificed to the gods. Digging inside the cenote during the previous season (R. Smith 1953) es-

tablished that water holes still exist and that they had been used in the Classic as well as in the Mayapán Period; but nothing pointing to the ceremonial casting-in of humans or objects, as had occurred at the Sacred Cenote at Chichén Itzá, was found by the investigations inside Ch'en Mul.

The mouth of the cenote is about 10 m in diameter and roughly circular. The temple is built on the south side, less than a meter from the present rim, so close, in fact, that a good deal of the collapsing superstructure has fallen into the cenote. The structure is approximately 8 m square.

Around the low substructure runs a cornice about 25 cm high; the wall below this cornice does not drop vertically, but has a definite batter or sloping zone. The plan of the building is not unusual and is somewhat reminiscent of the Xtoloc Temple at Chichén Itzá and the Cenote House at Tulúm. The entrance faces east where a balustraded stairway leads to a low, gently rising terrace, at the rear of which stand the plinth of the building and the remains of two columns flanked by door jambs. The column drums are of the low, rough type common in Mayapán; four stones of the south column and five of the north are still standing, and part of the originally thick plaster coating can still be seen on the bottom stones. Thus the original effect must have been that of a triple-entrance doorway to the temple interior.

One suspects from the absence of a thick layer of fallen plaster on the surface of the interior that this building did not have the common beam and mortar roof, but perhaps was thatched. Flakes of red-painted plaster indicate the probable color of the walls.

The altar, against the back wall of the building, behind two interior piers, was found to be undisturbed; the cache, in the center and very near the surface, consisted of two, badly crushed Red Ware tripod bowls laced lip to lip and containing a partly burned ball of copal.

The temple seems to have had only one primary building period, although renovations to the superstructure in the way of varying floor levels and bench construction occurred from time to time. Excavation under the stairway showed that the terrace wall is built directly on the thin layer of sterile earth overlying bedrock, and the same is indicated on the west side. The terrace between the stairway and the front of the building was thoroughly tested by means of a pit extending to bedrock, but under the two top plastered floors only heavy rock fill was encountered.

Last season, burial cists were found in most of the shrines and temples explored in the northern part of the Main Group. It was thought likely that this temple might hold a similar cist or shaft, but nothing of the kind was found. Thus the method of disposition of the

bodies of sacrificial victims, if there were such, is still uncertain. As was mentioned before, no skeletal remains were found in the cenote, although this does not rule out the possibility that corpses were thrown in and later removed. In fact, the closest indication of human sacrifice is a femur found on the west edge of the cenote, a highly doubtful piece of evidence.

The pottery found on the surface and in the various trenches is of the common Mayapán types. No vessels were found intact. Although a number of utilitarian ware sherds were uncovered, the largest percentage was, as might be expected in a structure of this nature, of ceremonial ware, mainly effigy-type incense burners. The exterior northwest corner of the temple, at the cenote edge, seems to have been used as a dumping place, for a great number of animal and bird bones and of sherds (mainly of incense burners, and fairly large) were dug out. From this dump too came a small turtle of a jadelike green stone, well polished, with a somewhat stylized head and body.

On the west and north sides of the cenote, retaining walls of rough stone had been constructed; the east side, from the temple to a ramp adjoining the long colonnaded hall, Structure Q-151, bounded by a low platform, the present height of which is less than a meter. Although from the surface this platform appears to be a single structure, it really represents construction of two different periods. The northern half is contemporary with a low stairway which was later covered by, the ramp mentioned above originally this part of the platforms free, but later it was joined to the northeast corner, of the temple by a southward extension of the platform. When this was done, it was necessary to make a drain under the south section to provide for drainage of the plaza floor. No attempt was made this season to clean the drain entirely of the rubbish which choked it, but many sherds, mostly of incense-burner type, and a number of large lumps of burned copal were recovered from the aperture on the cenote side. There can be little doubt that the platform had some part in the ceremonial functions centered about this important cenote.

The next unit investigated was a shrine or subsidiary temple, Structure Q-149, about 30 m southeast of Cenote Ch'en Mul and facing east toward a temple, Structure Q-143. It was decided to include in these investigations a small, low platform about 5 m east of, and centered on, the stairway of Q-149.

The shrine is typical of Mayapán architecture in most respects, consisting of a single room built on a substructure of moderate height. There is the usual plinth, but no columns, entry being made through a doorway formed by two monolithic jambs which still stand. To judge by the thick layer of fallen plaster inside the shrine, the roof had been a beam and mortar

affair. Several coatings of plaster were visible on the lower parts of the door jambs, the last showing small patches of painted designs in red, black, and green.

Inside the shrine the floor was cleared, and the altar, which had been centered against the back wall, was found to have been ripped out; its original position could be traced by the upturning of the floor around it. A small ho had been dug below the base of the altar through an earlier floor, and the destruction may well have been the work of looters.

When the terrace in front of the plinth of the building was being cleared, a large sculptured stone head was found. From near by came a hand and a leg of the same proportions. The head resembles two others recovered last season near the base of this structure, and it is probable that all three were at one time part of sculptured figures placed, perhaps, on the roof or over the doorway.

In order to ascertain whether this shrine, like others in Mayapán, contained a burial cist, a pit was excavated in the terrace before the plinth. No indication of such a construction was found.

Digging around the base of the balustraded stairway revealed that the original plastered levels of to plaza around Structure Q-149 there had been a rough stone layer which served as a base for a later floor. Built directly over this layer is a secondary wall which extends around the rear half of the shrine's substructure. Roughly U-shaped, about 60 cm thick and with a present maximum height of 1.7 m, it extends around the west side of the substructure and about halfway around the north and south sides. It is hard to believe that its purpose was to beautify the shrine; it may have been erected as a reinforcement for a weakened wall of the substructure.

The small platform in front of the stairway of Structure Q-149 is approximately square, about 1.5 m on each side, and at present only one course of stones high. It rests on the stone layer covering the original plastered floors of the plaza, and thus some idea is obtained of the building sequence. An excavation was made into the small earth-filled depression in the center, but nothing was uncovered. The purpose of this platform is uncertain; it may have been an altar-like construction, the base for a figure, or the foundation for a sacrificial stone such as is known to have been placed sometimes before stairways.

The other shrine or small temple excavated, Structure Q-148, is also a single room building on a substructure of moderate height. In spite of its proximity, it does not seem to have had any ritual connection with either of the structures just described. Rather, it appears to be aligned with the colonnaded hall, Structure Q-151, for its stairway, which faces north, is directly opposite the main altar of the hall.

Unlike Structure Q-149, and for that matter the vast majority of shrines at Mayapán, this building had a triple entrance doorway. A number of Puuc-style mask stones, some badly shattered, were observed on the surface even before clearing, and when the area between the door iambs was excavated, the lower sections of two pillars faced with similar elements came to light. The original height of each pillar as estimated from the fallen stones recovered, must have been at least 1.5 m. The stones, which roughly the sector of a circle in plan, the curved surface being the face, are laid one above another to form the front of each pillar. Some of the stones have designs and others are plain, but actually they were covered with thick coatings of plaster to give the impression from the outside of solid columns supporting the door lintel.

Centered against the back wall of the room was a masonry altar. A small flake of gold the size of a fingernail, bearing a faint design, was found in the debris near by. Also near the altar were discovered several large pieces of charred beams. These not only indicate that the shrine had, a beam and mortar roof, but lend some support to the old tradition of the destruction of the city before its sudden abandonment. The surface of the altar had been destroyed, and the presence of more fragments of charred wood in the earth inside makes one suspect that the altar was open when the roof burned. If so, and if looting had been the intent, the operation was not entirely successful, for between two front stones of the altar was found a small effigy vase containing two jade and three shell beads, a tiny fleck of copper, and a small jadelike flake of a mosaic. A copper bell and another shell bead recovered near by may also have formed part of the cache.

Excavations both inside and outside the shrine revealed several floor levels, which give some idea of the various changes in the original structure. A trench was dug in front of the building into the rock fill of the substructure, but just as with the temple by the cenote and the other shrine, no burial cist or shaft was found.

Digging around the walls of the substructure uncovered an unexpected secondary wall or facing running all along the east, south, and west sides. Like the secondary wall around the rear part of Structure Q-149, this construction may have been a means of changing the original design of the shrine, or it may have been a reinforcement to support collapsing inner walls. A similar structure (Q-154) a short distance southwest seems also to have a secondary wall around it. The thought occurs that this architectural feature may have been fashionable or significant at some period in this section of the Main Group.

40.22.

WILLIAM N. IRVING

Excavation in Mayapán

YB 53:276–277, 1954

The greater part of the field season was spent in the excavation of Structure Q-151, one of the larger colonnaded halls in the main ceremonial group at Mayapán. During the later part of the season a large residential unit, Structure Q-231, was surveyed, and a plan was made showing such details of construction as could be discovered by making limited spot excavations. Finally, observations were made and recorded on the techniques used at Mayapán for working in flint and obsidian.

The colonnaded hall, Q-151, by virtue of its location near the Castillo and Structure Q-152, the largest round temple at the site, and Cenote Ch'en Mul with its nearby small temple, is a prominent member of the main ceremonial group. Its excavation was expected to shed some light on the plan and the nature of the activities associated with such halls in general, and on the use of this building in connection with public functions in the center of the city. The structure was also considered suitable for partial restoration as representative of Mayapán colonnaded halls. Finally, there was promise that stratigraphic cuts would produce information to permit a finer demarcation of phases within the Mayapán Period.

The entire front of the building and substructure were cleared of fallen debris to the most recent levels of construction, from the west end to a point some 3 m east of an enclosed medial shrine set in the bench that runs along the rear wall. This excavation exposed a gallery that had formerly had a beam and mortar roof supported by two rows of columns and short wall sections, the bench and medial shrine just mentioned, and a shrine or altar at the center of the stairway. A notable feature is the installation of Puuc-type façade masks on masonry piers set between Columns 3 and 4 and between Columns 7 and 8 of the 10 columns in the front row. The city abounds in sculpture and stone decorative elements referable to the Puuc style, but this is the first instance of their having been, re-used as originally intended but in a Mayapán Period building.

Of particular interest are the results produced by the stratigraphic trenches. One, in a section of the filled passage formed by the rear wall of the colonnaded hall and the substructure of the round building, Q-152, was excavated to bedrock (ca. 2.5 m) by 50 cm levels. The pottery analysis, undertaken by Shook, showed that the hall was built rather earlier in the

Mayapán Period than had previously been supposed, well before the sudden proliferation of effigy incense burners and the development of certain late forms of utilitarian ware. The passage had apparently been filled alternately by the dumping of rocks and lime mortar, and by debris, presumably from the platform of the round building, which included human corpses and utilitarian as well as ceremonial pottery. The relationships of natural soil and substructures seen at the bottom of the trench indicate that construction of the colonnaded hall postdated that of the round temple.

A second stratigraphic excavation was made in the corner formed by the juncture of the west wall of the substructure of the round building and the rear wall of the colonnaded hall. This revealed a short bench along the former substructure which had been built over a deep (ca. 1 m) accumulation of midden material. The significance of this midden, in an exposed spot next to two prominent public buildings is not yet fully understood.

A trench cut through the center of the colonnaded hall from the bedrock front of the medial stairway to the shrine at the rear showed a building sequence marked by at least nine floors; several significant changes in the central altar at the rear of the building and in the shrine, which produced fragments of stucco and stone sculpture and a wealth of broken incense burners; and apparently one transposition of the supporting columns. It is hoped that a detailed comparison of these features with their counterparts in other similar halls will shed light on the development of this type of structure and perhaps on its intended use.

Structure Q-231, located less than 200 m from the Castillo, is considered to be a residential group, one that might well be described as a palace. It consists of two large dwelling-type structures on high platform mounds, and two smaller buildings on low platforms, the whole arranged in the form of a quadrangle. The small amount of digging done in connection with mapping its gross features suggests that the group would be an interesting one in which to continue excavations.

40.23.

H.E.D. POLLOCK

Excavations at Mayapán

YB 53:277–279, 1954

During the past field season Pollock undertook a number of limited excavations at Mayapán to ascertain needed architectural details and the chronological re-

lations of certain buildings. The first such excavation was concerned with the Castillo and Structure Q-163, a colonnaded hall that lies at the foot of the west stairway of the larger structure. A distance of less than a meter separates the east end of the hall from the lowest step of the stairway, providing an excellent opportunity to discover the relative time of construction of the two buildings. Our excavations revealed a series of eight floors, the lowest of which appeared to be contemporaneous with the construction of the stairway of the Castillo. This floor and the next above it ran beneath the plinth of the colonnaded hall. Floor 3 and all higher floors are well above the level of the bottom of the plinth. Unfortunately they are broken, within the area of our excavation, just short of the plinth course of the hall, a condition which can best be explained by root action, but which may hide the fact that the builders of Structure Q-163 cut through one or more of these floors at the time of construction of the building. What is clear is that the colonnaded hall, Structure Q-163, is contemporaneous with, or later than, Floor 3, and was built later than the west stairway of the Castillo.

The next two excavations involved the determination of roof heights of colonnaded halls. Owing to the relatively unstable construction of this type of building, little remains to give an indication of the proportions and general appearance of such structures in their original condition. At the east side of the Castillo a colonnaded hall, Structure Q-161, is built against the terraces of the pyramid, and on the west side of the pyramid another structure, probably a colonnaded hall, is similarly located. Because of the support provided by the terrace walls of the pyramid, these locations were likely spots to look for fragments of roofs still in position.

Our work at the west side of the Castillo was successful in uncovering what clearly was a section of the roof of the building below. This fragment was preserved in the angle between the south wall of the west stairway of the pyramid and a terrace wall. Excavation of the plinth of the building thus provided a height from floor to roof cap. Unfortunately, the great depth of debris against this side of the Castillo obscures the precise character of the building that had stood here, but there is some reason to believe it was a colonnaded hall.

Our work at the east side of the Castillo pyramid was less conclusive. No surely identifiable roof cap could be found. There were indications, however, that the roof of Structure Q-161 was on the same level as, and merely a continuation of the floor of the upper surface of the second terrace of the pyramid. This gave height above the floor of the colonnaded hall of roughly 3.7 m, a figure closely approximating that determined at the west.

Structure Q-159 is a small pyramid temple immediately south of the Castillo. Although very little of the superstructure, was visible before excavation, there was a columnar entrance at the east and the bare suggestion of a battered lower zone on the walls of the temple. The latter feature seems to be one of the characteristics of serpent-column temples at Mayapán, and the existence of a fallen fragment of a stone serpent tail on the northwest slope of the pyramid added to the possibility of the building's being of that type. Excavation quickly proved the existence of the battered lower wall zone and that the two columns in the entrance to the temple carried stucco figures at their bases. Instead of the expected conventional serpent heads, however, these figures were four-footed monsters, possibly Earth Monsters, although the stucco was not sufficiently well preserved to make identification sure. The finding of part of a stone serpent tail beside one of the doorway columns, a fragment that fitted the one previously noted, and of a second serpent tail off the southeast corner of the pyramid left little doubt that the doorway supports had been completed at the top in conventional serpent-column fashion. In other words, we had here a new and previously unknown form of decorative doorway column, part serpent, part monster. This is a type so far known only at Mayapán.

Further excavation developed a single-room temple building with an altar centered against the rear wall. In front of the altar was the stone figure of a turtle, fallen from its original position. There was nothing distinctive about the terraced pyramid, which carried a balustraded stairway on the east, in which direction the structure faced. Pottery from within the building, was mainly of effigy incense burners and a single sherd of Red Ware from beneath the floor, where only three sherds were recovered would seem to prove the temple to be of the Mayapán Period.

Another small excavation was directed to establishing the sequence of construction of three adjoining structures some 50 m east of the Castillo. Structure Q-143, a small pyramid-temple with serpent column doorway, is clearly older than Structure Q-142a, which abuts it at the north. East of Q-142a is the colonnaded hall, Structure Q-142, the west wall of the latter built against the rear wall of Structure Q-142a. From surface observation it was impossible to tell which of these two buildings was the earlier, but it appeared that the determination of this fact might yield a sequence of three buildings, because of the relationship of the pyramid-temple to Q-142a, all of different types.

Excavation readily revealed that the west wall of Structure Q-142 was erected later than Q-142a. A closer examination of Q-142, however, showed that the west end of the building almost surely was a later addition to the main body of the colonnaded hall to the east. We

were thus unable, without considerably more extensive excavation, to tie the primary part of Structure Q-142 into our sequence. Floor levels suggest that the original building is contemporaneous with, or later than, Structure Q-142a, but this was not proved. A tentative sequence of construction might be, from early to late, Structures Q-143, Q-142a, Q-142, west addition to Q-142.

Lastly, work was undertaken at the northern terminus of the city's principal *sacbé*, or artificial road, which connects two groups of structures roughly 400 m apart. Both groups are of the courtyard variety, the northern in Square R, the southern in Square Z, and probably were domiciliary in character, although they may possibly have served as community ritual centers. Our excavations were designed to discover the relative time of construction of the *sacbé* and the architectural assemblage at its northern end, and if possible to ascertain the period of the road in relation to the time of occupation of the site.

Although these excavations started as a strictly limited operation, the existence of a complex system of superimposed floors, platforms, and terraces led to turning over considerably more dirt than originally was contemplated. Approximately two weeks were spent at this location, and at the end there were several unsolved but pertinent questions that only much more widespread digging could answer. In the main, however, our purpose was achieved. It was perfectly clear that the building of the *sacbé* was at or near the end of the sequence of constructions uncovered by our excavations, and there were good indications that the road was late in relation to the entire group. Pottery from beneath the *sacbé* not only was almost purely of Mayapán Period, but contained an appreciable percentage of wares known to occur late in that period. It thus develops that the northern end of the *sacbé*, and presumably the entire road, was built late in the history of the city, a fact that was not without surprise, as at the time of these excavations no examples of Maya roads from this late period were known. It later developed that the explorations of Sanders this season on Cozumel Island off the east coast of Yucatán disclosed two roadways that may be of Mayapán Period.

40.24.

J. ERIC S. THOMPSON

Excavation of Residential Type Structures in Mayapán

YB 53: 279–281, 1954

Structure Q-208, situated about 80 m south of what may be the southern edge of the ceremonial center, was chosen for excavation because, from what was visible above ground, it appeared to be the residence of some important person, a type of structure not previously explored. The remaining structures were examined to see if, because of their contiguity, any functional relationship to Structure Q-208 could be established.

Structure Q-208 consists of one long room with an open front (north) with four columns. Doorways in the back wall lead to three small and narrow rooms, of which the central one served as a shrine. On the east end of the structure there is a fifth room, without direct communication with the other rooms. Walls are very largely built of re-used dressed stone of the Puuc Period, of excellent quality, and one of the four benches of the front room is decorated with squat spool ornaments typical of Puuc architecture. Heavy layers of fallen mortar showed conclusively that the roof had been of the beam and mortar type.

Great quantities of charcoal, some pieces of which retained the shape of sections of poles, were scattered through the fallen mortar and in some cases underlay it, supplying conclusive evidence that the building was burned. Because a beam and mortar roof could hardly burn and collapse as the result of an accidental fire, we can feel fairly confident that the destruction was deliberate. As ceramic evidence shows this to have happened at or near the end of the occupation of Mayapán, it is reasonable to suppose that the burning took place at the fall of Mayapán (circa 1460 AD). The absence of any noticeable accumulation of dirt between the fallen mortar and the floor, and the presence of offertory vessels on the floor at the entrance to the shrine, indicate that the building was in use at the time of its destruction.

There was no evidence that food was prepared or cooked in the building, but in view of present-day Maya usage (there is often a small hut for cooking behind the main house) that was hardly to be expected. On or slightly above the floor were several artifacts, including two finely polished celts (one of fine-grained greenstone, the other perhaps of basalt), a flint point, and two finely chipped arrowheads, one of obsidian and the other of flint. Unless the archaeologist in charge is directly looking over each shovelful of earth excavated,

it is difficult to know the exact depth of any stray find. Luckily, in the case of one of the celts, it is established that about 4 cm of roof mortar separated it from the floor. As it was close to the base of one of the columns, it is a reasonable conclusion that it was dislodged from some shelf or niche in the wall above the columns and lintels; had it been in full view, the burners of the building would surely have taken it. The second celt also was close to a column, but it is not certain whether it was directly on the floor or in, the fallen mortar. There was no domestic pottery on the floor; many, if not all, of the sherds in the debris had formed part of the ceiling mortar.

At the entrance to the shrine two effigy vessels representing the “diving god” stood before a fallen sculpture of what may be a variant rendering of the same deity. This is, for Mayapán, of remarkably fine workmanship. The cult of the diving god may be of Mexican origin. Beneath the building was an earlier structure of about the same size, and beneath the floor of that were the remains of several small children, one of whom had anklets of copper bells. Above the burials were many sherds of incense burners. Among these were fragments of five bearing effigies of the Mexican god Xipe Totec, easily recognized by the flayed skin he wears. Bishop Landa describes the flaying sacrifice, but as this ritual also had a part in ceremonies of certain Mexican goddesses, it had not previously been known beyond doubt that there was a Xipe cult in Yucatán.

There was no direct evidence of a functional relationship between the other buildings in this group and Structure Q-208, but in the case of two of them a connection may be surmised.

Structure Q-209, directly east of Q-208, was a small residential structure with two rooms, one behind the other, separated by a medial wall. Each room had two benches divided by a passage which pierced the low medial wall. In contrast to Structure Q-208, Q-209 was constructed of inferior masonry; the walls had been low and the roof of perishable materials. As Structure Q-209 stood on a platform separated by a shallow passage, only 59 cm wide, from Q-208, and was of later date, it is reasonable to conjecture that it was the residence of inferior members of the household of the chief who occupied Q-209; for it is difficult to imagine that he would permit strangers to build and occupy an addition to his dignified residence. Structure Q-208a was a small low platform standing on a sub-platform which underlaid that of Q-208. The platform is separated from the northwest front of Q-208 by only 1.3 m, and faces east. Although its sub-platform is earlier than Q-208, the present, simple platform may be of later date. It supported no structure, and no evidence of its use was obtained. Nevertheless, its contiguity to Q-208

and the fact that it faced on the court in front of the latter suggest a connection.

Structure Q-207 occupies a commanding position on a natural hillock immediately south of the east end of Q-208, and faces east. Access was by means of a stairway conforming to the natural slope. The front room had three benches and was open on the east side. Two doorways gave entrance to a long, narrow room behind. This, in turn, had a doorway leading to a shrine room in the rear. Walls were low, and masonry was of inferior quality. A preliminary study of sherds from beneath the floors seems to show that Structure Q-207 was anterior to Q-208. This, together with the eastern orientation of the building and its staircase, argues against a close association with Q-208.

GUSTAV STRÖMSVIK

*Exploration and Reconstruction in
Mayapán and Vicinity*

YB 53:281–282, 1954

Toward the end of October, when the extraordinarily heavy rainy season of 1953 approached an end, Strömsvik began the previously planned exploration of the vicinity of Mayapán. The purpose of this work was to gain some idea of the extent of Mayapán culture during the principal period of occupation of that city and to note any ruin of different cultural affinity or of different period. Several groups of ruins were found, the most important being Xcanyulmil, about 4 km south and slightly west of the Castillo in Mayapán; Xpopil, roughly 3 km west-southwest; and Santa Cruz, a little over 2 km south and slightly east. Such groups are usually built near cenotes, each site consisting of a central pyramid structure around which are terraces and smaller mounds. With the exception of Santa Cruz, these sites appear to be of Mayapán Period. Santa Cruz seemed somewhat different. It is more widely spread, and the pyramidal structure is small and seemingly of little importance as compared with those at the other sites. Furthermore, at a platform some distance from the center of the ruins were found potsherds that appeared to be of Puuc type. The site was suggested as offering possibilities in the search for ceramic stratigraphy. Sketch maps were made of the three sites.

With the beginning of large-scale operations at Mayapán the middle of January, Strömsvik undertook a series of small excavations in connection with Proskouriakoff's detailed mapping of the main ceremonial group at the site. This work was designed to develop plans of buildings and hidden details of architecture preparatory to Proskouriakoff's mapping. With the exception of a week given to exploration in Quintana Roo with Pollock, the work continued until the middle of March.

In accordance with an informal agreement made the previous year with the Instituto Nacional de Antropología e Historia of the Mexican Government, Strömsvik took charge of the consolidation and repair of two structures typical of Mayapán architecture. The buildings selected for such treatment this season were a large colonnaded hall, Structure Q-151, just east of the Castillo, and a house-type building, Structure Q-62, adjacent to another colonnaded hall at the northern edge of the Main Group.

Structure Q-151 was excavated by Irving. A little over half of the building was cleared of debris, as it was thought that this part of the structure, which included the centrally placed shrine and altar, would provide a clear understanding of the colonnaded hall. Walls were rebuilt with lime and cement mortar to the height that they stood when excavated. Columns were reset to a height less than that of the back wall, but sufficiently high to indicate their function. For the sake of permanence, lime and cement mortar was placed between column drums instead of the mud mortar that originally had been used. The original 3–5 cm thick lime plaster covering that had encased the columns was not reproduced. The decorative masks on the façade of the building were rebuilt as, completely as available parts allowed.

Structure Q-62, considered to be a good example of simple, living quarters in Mayapán, was excavated by A. L. Smith and Ruppert. Walls and benches were reset in the original manner, and the over-all plan, room arrangement, porches, passageways, and benches, was made clear to the observer. The low walls of masonry had once, of course, supported wood and thatch construction, which we did not attempt to reproduce, as such material would fall prey to the elements in a few brief years.

This task of reconstruction and the not inconsiderable labor of clearing away the tremendous quantities of debris that had accumulated from the excavations lasted until well into June. The work was interrupted the last week of May to make a second trip, this time accompanied by Berlin, to the ruins in Quintana Roo that had been visited earlier in the season by Pollock and Strömsvik.

40.26.

ROBERT E. SMITH

Pottery of Mayapán and Vicinity

YB 53: 282–284, 1954

The number of potsherds collected at Mayapán during the 1954 field season totaled nearly 130,000. A very large percentage of these belonged to the late Mayapán period and were found on or near the surface. Earlier Mayapán Period types (Black on Cream, certain Red Ware shapes, and certain styles of incense burners) were located below floors or in deep stratigraphic cuts, most, of which were associated with ceremonial structures. The ceramics from ceremonial structures have been discussed by Shook [Chapter 40.13]. The trends noted by him are essentially the same as those seen in the pottery from elsewhere in Mayapán. Differences worth mentioning are that effigy censers occur in considerably greater proportion in the house mounds, often elaborate, of the ceremonial center than in the simpler house mounds spread over the site, and that Black on Cream pottery forms a small percentage of the types associated with the house mounds of the ceremonial center and is rarely found in those outside. At present, our knowledge of house mound pottery is limited to the excavation of a few domiciliary structures both inside and outside the ceremonial center. Nevertheless, there is a suggestion that the more elaborate style of domiciliary structure harbors a more elaborate style of pottery, for example, effigy censers, effigy vessels, and rather large painted figurines. Also it is probable that most of the house mounds excavated belong to the Mayapán Period, since the ceramic types of that time are predominant. In fact, the ceramic types of earlier periods taken from all house mounds, excavated from 1952 through 1954 will not form 1 percent of the total house mound pottery. On the other hand, the house platforms of the small outlying site Santa Cruz abound in early potsherds.

The ruins of Santa Cruz are situated about 1.5 km by trail southeast of Cenote Ch'en Carro, which is located in the south-central part (Square Y) of Mayapán. These ruins, which occupy a relatively small area, roughly 200 by 300 m, part of which is used for pasturage and part for growing corn, squash, and peppers, were recovered and mapped by Strömsvik in November 1953. There are in all eight platforms and a small pyramidal structure. This last and five of the platforms are clustered around a sizable jug-shaped cenote which contains what the natives claim to be the coolest, freshest, and most palatable water in the vicinity. The platforms have been numbered from A to H. Only three

were investigated: A, the farthest north; B, just northwest of the cenote; and C, due east of the cenote.

The investigation of Platform A consisted of digging three trenches. The West Trench disclosed the original west wall of the platform to a depth of about 1.5 m. This wall was constructed of large and medium-sized stones and was probably built during the Puuc Period; both the appearance of the wall and the ceramic evidence from inside the platform support this suggestion. The sherds from the three strata in this trench were all of pre-Mayapán Period pottery save for one possible effigy-censer fragment found in the top stratum. The proportion of Formative to Puuc Period types increased from top to bottom.

Perhaps the most instructive of the three trenches was that dug alongside, but not directly next, the north wall. After sinking an exploratory pit well to the west, and finding only Puuc and Formative pottery types except for a single effigy-censer sherd, we prolonged the pit into a broad trench. Two infant burials, both in Puuc-type jars, and two Puuc Medium Slate bowls, apparently associated with an adult burial, were encountered in stratum 2. Very few artifacts were found in the North Trench, all in stratum 2. The ceramic pattern resulting from the three levels excavated resembles closely that of the West Trench with a greater abundance of early types. An interesting fact about this trench is that it appears to have cut through a refuse deposit, at least in the western section.

The East Trench passed through several terraces and finally bisected a single-room shrine at the north edge of the platform. A number of floors at different levels were encountered. Close to the surface at the south end and above the top floor in the shrine at the north end, two rather crudely made, small Mayapán Red vessels were found, whereas about 1.3 m below the top floor and sealed beneath the earliest and best-preserved floor a formal Puuc Period crypt burial was encountered. This burial contained an adult male skeleton, three Puuc-type pottery vessels, a number of jade, shell, and bone ornaments, and five jaguar teeth. Few artifacts were found in the middle and top levels. The ceramic pattern derived from the three levels in the East Trench differs considerably from that of the West and North Trenches. More Mayapán types occur in the top level and fewer Formative types in the bottom.

Platform B supported several house platforms, two of which, and an altar, were investigated. The latter were enclosed within a walled area in the southwest part of the platform. For the most part the walls appeared to be of post-conquest construction, possibly quite recent, but with some sections presumably dating from ancient times. In order to determine the manner in which Platform B was built, as well as to collect a pottery sample, a broad trench was cut into the north

side. This North Trench uncovered at least three terraces and two floors. Very few artifacts were found, all from the surface level. The ceramic pattern disclosed by the five levels excavated resembles that of the West Trench in Platform A.

House Platform 1, rectangular in plan and located in the southeast corner of Platform B, was bisected by a trench reaching to bedrock. Just south of the house platform a cache was encountered 68 cm below a fallen monument or, if not a monument, possibly a door or gate jamb. The cache contained two vessels, one a lustrous, streaky brown jar, the other used as its cover, a Puuc Medium Slate tripod dish with red floor design. Near the cache but above it, two flint points were discovered, one especially well made. Within the house platform there was a fairly good floor 32 cm below the surface, and 86 cm below this floor, just inside the south edge of the house platform, a burial with three pots was found. Most of the skeleton, an adult, was lodged under an enormous rock. The vessels, one of which covered the skull, were all Puuc Medium Slate types. The pottery found in the trench totaled only 185 sherds; because of a cave-in during the removal of the burial vessels, some late sherds were mixed with material from the lowest level. The middle level however, had no pottery later than the Puuc Period.

House Platform 2, rectangular in plan and located just northwest of House Platform was examined by means of a 40 cm deep trench skirting its northern half. Later a pit was sunk to bedrock off the west side, in the upper 40 cm of which a quantity of Mayapán Period porous gray jar sherds were uncovered. They rested in ash and were surrounded by medium sized stones, as if some ceremony had been performed, but the sherds were not burned. All levels associated with House Platform 2 had a preponderance of Mayapán types.

Approximately 9.5 m due east of House Platform 2 a small altar was investigated; directly west of it a cache of five Mayapán type vessels was found buried 20–70 cm below the surface. The vessels consisted of a large porous gray jar, a red tripod dish with effigy feet (human head with turned-up nose) a small red jar, a red cylindrical tripod vase, and a complicated and badly damaged effigy vessel. Nothing remained of the altar save a large rectangular stone set on edge, facing which was a rectangular paved area. The cache was just west of this paving.

Originally Platform C may have supported three single-room shrines consisting of two nearly square structures opening north and south, respectively, and flanking a larger rectangular construction that faced Cenote Santa Cruz to the west. There is now no trace of a shrine on the south side, but there is ample space on the platform for it. Both existing shrines originally had beam and mortar roofs and a centrally located altar or

dais. The pottery collected in the two trenches which cut through the doorways of these shrines and descended to bedrock was predominately of Mayapán Period with little change from top to bottom. On the other hand the ceramic pattern indicated in the three levels excavated in nearby Cenote Santa Cruz was one of increase in early types at the expense of late types as the pit progressed downward.

From the ceramic evidence it would appear the Platforms A and B were originally constructed during the Puuc Period and that both were subjected to later building activity. Platform C suggested only late, Mayapán Period construction.

The next work undertaken was at the large mound in the village of Telchaquillo. This ruin, situated south of the cenote in the Main Plaza and still standing after all the years of stone robbing for village property walls and house foundations, remains an impressive mass of masonry. The principal aim in trenching into this large complex was to determine something of its age through its growth, both horizontal and vertical. It was by reason of the horizontal accretions with their time-sensitive pottery inclusions that a chronological sequence developed. That this sequence did not evolve into something more conclusive is probably due to the fact that the mound was not penetrated sufficiently far. The reason for not continuing deeper was the excessive outlay in time and labor that would have been required. The two trenches, one on the south, the other on the west side, each penetrated through several terrace walls. In the pottery lots, Puuc types were always more abundant than Mayapán. Actually, the farther into the mound we progressed, the greater became the predominance of Puuc over Mayapán types. The fact remains, however, that Mayapán wares were always present. The ceramic trend suggests that farther inside the mound a pure sample of Puuc pottery might have been encountered.

40.27.

TATIANA PROSKOURIAKOFF
Art and Artifacts of Mayapán

YB 53: 285–286, 1954

This season's work has substantially advanced our knowledge of the artistic styles at Mayapán, which document the decay of Maya culture. We were extremely fortunate to uncover a portion of a mural painting on the wall of the front gallery of a large temple, Q-80. The

wall is broken by five niches, which, in the composition of the painting, represent doors of buildings depicted around them. The buildings apparently stand on a terrace represented by a black dado at the base of the wall, interrupted, however, by the niches, which extend to floor level. Between the niches on the black dado are depicted heads of monsters with open jaws, which strongly resemble serpent heads carved on the columns of Structure 2C1 at Chichén Itzá. These heads are painted in vivid tones of green, red, yellow, and blue, and in white. Above them the mural is largely destroyed, but by combining the scattered features still preserved, one can reconstruct the outlines of the houses that frame the niches.

The upper zone of each house consists of a narrow vertical zone between typical Maya two-member (fillet and bevel) moldings. Below, the walls are not vertical, as in most Maya buildings, but are composed of two sloping zones, the upper one projecting slightly beyond the lower. Some of the buildings at Mayapán have a sloping lower zone, but the upper slope is seen for the first time on this mural in connection with a Maya building. The houses are painted on a red background, and their walls and moldings are brightly decorated with geometric designs in polychrome, largely composed in bands and outlined in black. Around each niche is a T-shaped form framing the lintel and jambs in the manner used in Mexican codices.

The mural extends almost to the vault spring of the gallery, above which there are no traces of plaster to show whether or not the painting was continued on the soffit. Unfortunately the condition of the plaster and of the masonry behind it is such that it would be very difficult either to remove the painting or to consolidate it in place. It has been carefully reburied in earth and masonry debris, which will keep it better preserved than could any possible attempt at restoration.

The sculptural style of Mayapán, so little known because of the poor preservation of monuments on the surface, is slowly beginning to emerge from a number of smaller, carvings coming out of excavations. A grotesque figure, examples of which range between 15 and 45 cm in maximum dimension, appears to be a type of ceremonial object associated with shrines of houses and colonnaded halls and in some way to be related to household worship. Two of these carvings representing turtles have a hollow receptacle on the back. The turtle motif strongly prevails and is usually accompanied by anthropomorphic features. In some cases, the turtle has a human head; in others, a human head is held in the mouth. There are also crouching human figures, some with a mantle on the back strongly suggestive of a carapace. One sculpture, recovered from a house (Structure R-88), seems to represent an armadillo with a human figure on its back. On

the sides of the carapace are carved the glyphs 4 Ahau and 13 Ahau, and on the back of the human figure is 1 Ahau. A much smaller carving of a turtle is made of fine polished green stone and is executed with admirable simplicity.

Most of the artifacts recovered this year fall into classes found in previous seasons, but a small fragment of ancient cord and cloth adhering to some copper bells, and preserved by the action of the disintegrating metal, is an unexpected addition to the list. Also new are two fragments of green obsidian, which is rare in Maya collections. The finds of jade continue to be meager and of poor quality jade is used mostly in the form of beads, often marred by fire, though there are several well polished jade disks 3–4 cm in diameter, perforated in the center. Shell beads occur in greater numbers, many in the form of perforated tinklers. Teeth, antlers, sting-ray spines, and bones are also represented, and several more greenstone celts have been found.

Chipped flint implements have produced no strikingly new forms, but the number of arrowheads is increasing both in flint and in obsidian, with the “expanding stem” formed by side notches prevailing as the common form. Also increasing, is the incidence of small obsidian scrapers and other tools made by re-touching flake blades.

Limestone tools and occasional tools of harder volcanic and granitic stones continue to come in, but the use of roughly chipped limestone disks about 10 cm in diameter remains a puzzle. They have sometimes been designated “pot lids” but with very little justification.

The items listed in this year’s catalogue amount to 294, making a total of 761 for the Mayapán project so far. Since shell beads, copper bells, and other small objects are often listed in groups, the actual number of individual specimens is much greater, even if we exclude the sizable collections of obsidian flake blades and of flint chips, which are not listed but are being held for future study.

40.28.

KARL RUPPERT AND
A. LEDYARD SMITH
Mayapán, Yucatán

YB 54:269–271, 1955

The square-by-square surface examination of the building remains at Mayapán having been completed

during the 1954 field season [Chapter 40.18 this volume], the 1955 season, with the exception of two weeks, was spent in excavation at the site. One week not consumed in excavations was used in checking a survey of house types lying within a distance of about 12 km from Mayapán. This survey was undertaken by three laborers, residents of Telchaquillo. The other week was spent at the ruins of Chacchob. At the end of the season A. L. Smith and Strömsvik made a one-day trip to Tulúm, a walled site that has many architectural and ceramic similarities to Mayapán.

During the season Ruppert and A. L. Smith excavated 26 structures at Mayapán. The purpose of this work was twofold: to try to get, through thorough excavations, sealed samples of pottery, and to determine the possible functions of the structures investigated. During the three previous years, Ruppert and Smith had devoted several weeks of each field season to excavations in various structures throughout the site, with emphasis on the average dwelling. This year some of the more elaborate dwellings were chosen, as well as structures with unusual ground plans. In the selection of structures for excavation, their distribution was taken into consideration, so as to have examples from all parts of the site. Several whole groups were also excavated. These consisted of elaborate dwellings with beam and mortar roofs, thatch-roofed dwellings, and simple low platforms with no traces of superstructures, arranged, in each case, around a court with an altar or altar shrine in the center.

In most cases the more elaborate variety of building investigated had two or more columns, built of stone drums, dividing the opening in the front wall into three or more entrances; the masonry was better than average, more Puuc type stones were used, and roofs were of beam and mortar. In one instance, Structure J-71b, there were masonry piers instead of round columns. In another very elaborate dwelling, Structure Q-244b, the upper part of the façade had so fallen that it showed there had been five courses of stones measuring about 60 cm from the supporting beam to the top. There was also one jamb still standing to a height of 1.7 m, which, plus about 20 cm for the beam supporting the upper façade, gave a total height of 2.5 m for the building. The presence of quantities of charcoal and the remains of burned beams on the floors of some structures with beam and mortar roofs indicated that they had been burned.

Types of structure other than the typical dwelling were altars, altar shrines, one room constructions with two columns in the opening in the front wall and two columns inside the room, and one-room structures with or without columns in the front opening. Buildings of the last type may have had a bench around three sides with a recess in the center of that part of the bench

extending along the back wall, forming a small shrine or altar (Structures P-28b and R-171b). In one instance, Structure Y-8b, such a structure had a passageway through the bench along the back wall leading into a shrine room which projected behind the building. Two constructions, Structures R-126a and Q-37a, each of a single room with two columns inside the room, had benches on three sides with an inset in the center of the bench along the back wall. Structure R-91, also a one-room building with two interior columns, had no bench but had a raised area in the center of the back wall. Four stucco human feet on the floor directly in front of the altar and stucco remains on the altar indicated that it supported two seated figures. Structure P-23c differed in that it had only one interior column, placed in the northern half of the room. There were benches along the back wall and north side, the former having a central recess. A doorway led out of the south end of the room. An interesting feature of this structure was an outside platform, abutting the north end, with postholes in the outer corners. The presence of ash and three metates strongly indicates that this was a kitchen. Another type of structure excavated faced in two directions, the opening on each side being divided into three doorways by two columns (Structures J-71a and S-133b).

As far as function goes, there is no doubt that the buildings which so closely follow Landa's description of house constructions in Yucatán (Tozzer 1941) were used as family dwellings. These are structures with a front room, open along the front, with benches and with one or more passageways leading into a back room which may or may not have had, benches or an exterior doorway. There is also no doubt about the functions of altar platforms or altar shrines in the court of a house group. These were surely family shrines. Sometimes altars and shrines occur inside or are a part of a dwelling. Platforms with no signs of superstructures are a problem, as they may have supported wooden structure which could have served many purposes, such as kitchens, temporary shelter for guests, etc. The one-room structures with benches and altars and sometimes with interior columns could have been used as dwellings of priests and served a religious purpose as well. They certainly would not lend themselves to a family group. Structure R-91, a single-room building with two interior columns, no benches, and an altar supporting two stucco figures, must have had a purely religious function.

Several of the structures excavated had earlier constructions under them, and sealed samples of pottery were recovered. All had sherds from the Mayapán Period.

In the course of digging a good many burials were encountered. These occurred in simple cists and in well made vaults, and bore out evidence from former years that there was no definite rule about burying the dead,

both method and location varying greatly. Two particularly interesting stone-lined burial vaults were found under benches in the east room of Structure S-133b. These vaults could be entered by means of low, narrow passages through the wall of the room to the west.

Grave furniture is scarce at Mayapán, but mention should be made of copper rings and a pair of copper tweezers among the objects recovered. Of interest was a complete pottery doll with articulated arms and legs.

During the first part of April, Ruppert and Smith spent five days at the ruins of Chacchob, a walled site visited by Pollock and Strömsvik in 1952 [Chapter 40.15]. The purpose of the trip was to investigate the house types at the ruins and to get pottery samples. According to Pollock and Strömsvik, all the structures they saw seemed to be of the Puuc period. The house structures investigated by Ruppert and Smith proved to be of this period, containing only Puuc types of pottery, with the exception of a small single-room building, possibly a shrine. This latter which was partly built of re-used or discarded Puuc-type stones, contained Mayapán pottery, showing that the site was occupied in Mayapán times.

Throughout the season two or three men were employed in searching the environs of Mayapán within a radius of about 12 km for house structures, the purpose being to find how far the types found at Mayapán extended outside the site. They visited 111 sites, consisting in most cases of a few structures associated with a cenote. Rough plans were made of structures; and samples of pottery were recovered when possible. Near the end of the season Ruppert and Smith spent about a week checking the most likely sites, and found that at only two were there houses of recognizable Mayapán types as far as 12 km away. These were the sites of Itzin Can and Xtubi Ch'en, both to the west. In all other directions Mayapán house types disappear within 3 or 4 km.

an unusually elaborate residence and suggested three points of interest on which we based our plans for the present investigation. Primarily, we were interested in the sequence of major building operations and in the ceramic types accompanying each stage. This, we hoped, would give us some idea of the length of occupation and of possible changes in the function of the group in addition to providing sealed deposits for ceramic study. Secondly, we looked for tombs, expecting to find in them ceremonial and luxury objects appropriate to a rich household. Finally, we planned to excavate what we surmised to be a kitchen, since none had been surely identified elsewhere at Mayapán.

We found that the building site of the quadrangle was unoccupied during the early period represented by so-called "Puuc" Slate and coarsely striated pottery wares, although a few sherds of this period turned up in soil overlying bedrock. The later Black on Cream Ware associated with the earliest constructions of the main ceremonial group was also virtually absent here, and we concluded that a considerable period of time had elapsed between the foundation of the ceremonial center and the building of this residence. Extensive rebuilding and numerous minor alterations, however, led us to believe that the group was occupied at least for the span of several generations before its final abandonment, which in all probability took place when Mayapán was violently destroyed in the middle of the fifteenth century.

The original plan included a broad terrace supporting two building platforms joined at a right angle, and a vaulted underpass near the juncture. We are not sure which way the group faced at this stage, but soon afterward a monumental stairway with a central shrine was built against the east terrace wall. Later, the main terrace was extended forward and to the north, the building platforms were lengthened and broadened, and their superstructures were several times rebuilt before, with the addition of new structures, the quadrangle assumed its final shape. Although too little of the earlier plans was recovered to ascertain the original function of the buildings, the general similarity of early and late arrangements and the continued use of an early shrine gives the impression that the group was planned from the beginning as a residence. At the end of its occupation, at least two of the principal buildings were destroyed by fire, evidently very soon after their inhabitants left, for a number of abandoned pottery vessels were found broken but still in place under the debris of burned roofs, although all articles of value had been removed from graves and caches.

The looting of the caches disappointed our hopes of finding luxury items intact. Of the prized materials, only a few jade and shell beads were recovered, several

TATIANA PROSKOURIAKOFF AND
CHARLES R. TEMPLE

*Excavations in a Large Residence at
Mayapán*

YB 54: 271–273, 1955

Preliminary mapping and excavation in Group R-85 to R-90 in 1954 [Chapter 40.19] established that it was

copper bells, and some minute fragments of thin gold. In Structure R-86, however, we came upon a plundered tomb that had been refilled to the brim with ceremonial objects, evidently collected and either purposely cached or simply dumped as too cumbersome to carry away. Among other things, the tomb contained several small sculptures, a huge number of fragments from figure censers with some well-preserved heads of deities, and various restorable pottery vessels of distinctive late types.

This cache or dump explains the lack of ceremonial material in the central rear rooms of house structures R-86 and R-87. These rooms contain altars and probably served as domestic shrines, although the only ritual object we found in place was a small sculptured turtle in Structure R-87. In both rooms there were large storage jars thickly coated with plaster, and in one corner of the room in Structure R-87 there was a small drain formed by a jar neck set in the floor. These features, implying the ceremonial use of water, were quite unexpected. One wonders if some form of ritual bathing was practiced here, especially since we have found no other facilities for this custom at Mayapán, such, for example, as the sweat houses of Chichén Itzá.

The excavation of Structure R-86a proved to be particularly interesting because this structure, which was a kitchen, as we previously guessed, was abandoned with most of its pottery equipment intact and gives us a good idea of the range of utensils used in cooking. The kitchen is actually an integral part of Structure R-86, but it also served Structure R-87, communicating with both houses by doorways and also by small apertures in the end walls of their front galleries. The main walls and columns of the kitchen date back to a time before either house was built, and it is not clear whether it had also, served as a kitchen for earlier houses. In its final form, it was a room roughly 5 by 6 m, with a large L-shaped bench on its west side, and a smaller bench on the east, partly blocking what was originally a wide entrance with two columns that now faces the end wall of Structure R-87 across a narrow corridor. Another wide opening, leading to an open colonnaded gallery on the south, is blocked by a low wall against which is placed a hearth. This rests on the finished floor and consists of three flat stones, originally partly surrounded by a semicircle of upright stones, of which only two remained in place. There may have been a similar hearth on the east bench. Between the two hearths, in the corner of the room, stood a large water jar and several other vessels. More vessels were grouped on the two benches and fragments of others were scattered on the floor. There was no dirt or other debris under the burned beams and plaster of the fallen roof to suggest that the room stood abandoned for any length of time. The pottery is

all of very late types, some of which have slightly convex rims, foreshadowing the peculiar form of the "parenthesis" rim of the colonial period.

Surprisingly few stone artifacts were found in the kitchen. Smaller articles may have been carried away, but the absence of manos and metates shows that corn was ground and prepared outside, probably in the open colonnaded gallery back of the kitchen. A number of metates, manos, and other stone utensils were scattered on the surface in the gallery, in the debris at the foot of the outer terraces, and near a stairway on the west that leads to the kitchen entrance. A few meters to the north of this stairway, where a trench had been opened, to expose the base of a terrace, we found a number of large, very roughly chipped flint tools, some of which resemble crude axes.

In search of early pottery levels, we dug another trench at the outer opening of the vaulted passageway just east of the kitchen. Here we exposed a deep stratum of ash filled with animal bones and fragments of pottery, apparently a kitchen midden that had been leveled to build the latest minor additions to the outer terraces. The pottery collection from this midden, although it includes a few simple figurines, contains almost no censer sherds and represents, almost exclusively, utilitarian wares with an unusually high proportion of lightly striated unslipped gray sherds. The animal and bird bones recovered have been brought to the United States for identification in the hope that they will furnish significant data on the dietary habits of the Maya. Since the ash layer covers early construction, and later additions are built upon it, the collections should be well placed in time when all the implications of the stratigraphy are worked out.

40.30.

J. ERIC S. THOMPSON AND
DONALD E. THOMPSON

*Excavation of a Residential-Type Group in
Mayapán*

YB 54: 273–275, 1955

The group formed by Structures Q-169 to Q-173 was excavated as a part of a program initiated last year [Chapter 40.25 this volume] to investigate supposed residences of the nobility. It is situated immediately

southwest of the Castillo, closer to the hub of the ceremonial center than one would expect to find a residential group, and is composed of six buildings. Three of these are built around a small court, open to the east, in the center of which stands Structure Q-170, a small shrine.

Structure Q-169, the most important building, stands on a fairly high platform occupying the south side of the court. Such of the building as was exposed before excavation indicated that it was a residence of persons of consequence. It comprises a long room with four benches and an open front with four columns, two narrow rear rooms, and a west room with two benches, exterior doorways, and access to the front and west rear rooms. Masonry throughout the building is unusually fine; much of the stone is re-used Puuc type. Drums of columns had been cut with more care; than was customary at Mayapán; indeed, several fall little short of being truly cylindrical. Thick layers of mortar above the floor were conclusive evidence that the ceiling had been of beam and mortar type. A small altar (looted before the collapse of the roof) set against the back wall of the larger rear room and along the central axis of the building is indicative of a private shrine, but no incense burners were on or near it, or in any other part of the building, a situation paralleling that encountered in the large residence (Structure Q-208) excavated last year.

Unfortunately, the floors were entirely free of artifacts which might have helped to clarify the function of the building. Certainly no kitchen was there, and there was no evidence that pottery vessels for eating or even to hold drinking water were kept in the building.

Below the front room and immediately in front of the central doorway to the rear room and altar is a large tomb, the floor of which is below plaza level. The roof is in the form of a crudely corbelled vault, the top of which had apparently been closed with wooden beams or planks in place of the usual capstones. In the tomb were a partly disturbed supine burial, 12 small and crude tripod bowls of Mayapán Red Ware, a handled brazier, and one copper bell. The last was partly hidden under a shin bone. As copper bells are not believed to have been used singly, and in view of the disturbed condition of the burial, it is probable that looters entered the tomb, but overlooked one bell, before the roof of the building collapsed.

The small building in the center of the court yielded no fragments of incense burners or other evidence of having functioned as a religious building, although its size and location suggested that it had been a shrine.

Structure Q-171, on the north side of the court, was a thatched building. There is a long room with benches and open front, narrow rear rooms, and an

exterior bench at the east end. It obviously was residential, but it is difficult to suggest the relation between its residents and the occupants of Structure Q-169.

Structure Q-172, a beam and mortar-roofed building occupying the west side of the court, proved to be of considerable interest because one of its two rooms was clearly for ceremonial use, whereas the other appears to have been residential. Room A contained an altar set against the back wall and benches against the flanking walls. Along the top of the altar, at the back, were the badly smashed remains of about a dozen incense burners. Below the dais-like step in front of the altar was an ossuary holding the jumbled remains of five persons and a pair of copper tweezers. Inside the altar was a well made pottery jar, with a tripod bowl set as a lid in its mouth and sealed in position with mortar. The jar was two-thirds filled with a very fine ash mixed with small fragments of bone. This is the first cremation in a sealed jar found at Mayapán.

Bishop Landa mentions the depositing of cremated remains in large casks over which temples were built, and he also writes of the offertory rites to the ancestral remains which, together with their idols, were kept in the oratories of nobles' houses. Although Landa describes more elaborate rites than the sealed cremation of Structure Q-172 suggests, the placement of this carefully sealed crematory jar beneath the altar does give the impression that a cult of ancestor worship, not unlike that described by Landa, had developed at Mayapán and had its focus in the private family oratory.

All in all, it is highly probable that this Room A of Structure Q-172 served as the private chapel of the residents of the group or, perhaps, only of the family resident in Structure Q-169. In contrast, Room B, from which there was no direct access to Room A, shows no evidence of having served religious ends. It contains two large and handsome benches, one against the west wall, the other against the north wall; and its main doorway does not give on the court, but is on the south side (a doorway giving on the court had been blocked). Clearing of the room revealed no clues to its function. As we have no reason to suppose that professional priests were employed to minister in family oratories, it is highly unlikely that this room was a priest's residence. There is, however, information that in some parts of the Maya area, including Yucatán, men retired into seclusion for the periods of fasting and continence which preceded many, probably all, ceremonies, both public and private. Indeed, segregation of male participants before and during a religious rite is still practiced in Yucatán. It is, accordingly, possible that this room with its benches adjacent to the oratory was reserved for occupation by the men of the group before some important ceremony, of the family if not of the whole community. That the main doorway of this room

is close to the side steps to Structure Q-169 may be significant.

Structure Q-173 is a small, irregular building with thatched roof which is off the court and faces South, just west of Q-172. Excavation supplied no evidence as to its function beyond the fact that benches divided by a medial wall suggested a residence. Plausibly it was the home of menials who served the occupants of Structure Q-169.

In the angle between Structures Q-172 and Q-173 was a most unusual construction. This was a quadrant-shaped room which presumably served for storage, since access to it was through the roof or through an opening in a now fallen part of the wall above floor level. The floor of the room was largely bedrock, with an irregularly shaped crevice in the middle. The position of the room (between the back walls of two structures) and its appearance and construction suggest that it was used for water storage, but the walls of the crevice are not now waterproof. The absence of broken storage jars and the presence, in a pocket of the crevice, of the pieces of a shallow tripod bowl with effigy feet hardly support the suggested use as a cistern. Alternatively, the room may have served as a granary.

The western part of the front room and the west rear room of Structure Q-208, not excavated last year, were cleared this season in order to complete the tally of imperishable objects that looters may have rejected or overlooked before they set fire to the building. Ash and charcoal in great abundance in the west rear room showed that here too the ceiling had been set afire. The only artifacts, apart from a miscellaneous lot of sherds, some from the roof mortar, were one unretouched obsidian blade from a core, and three matching human effigy feet from a bowl of Mayapán Red Ware. As no other pieces of the bowl were found, it seems probable that these feet, to one of which a section of base still adhered, had some secondary use. Could they have been a child's playthings?

40.31.

DONALD E. THOMPSON

Excavations at Mayapán

YB 54: 275–276, 1955

The major part of the season was spent in excavating for architectural features at the Itzmal Ch'en ceremo-

nial group, reported by Chowning, and in a thorough examination of the latest period of a residential group reported by J.E.S. Thompson and the writer. Toward the end of the season, Structure Q-165, herein discussed, was investigated because of its proximity to both a colonnaded hall and a residence, Structure Q-168, excavated by Chowning. It was hoped to discover, if possible, the function of the building and its affiliations.

Structure Q-165 was composed of two rooms connected by a doorway. The larger and main room faced a small court on which the residence, Q-168, also opened. The colonnaded hall, in line with Q-165, faced in the opposite direction, though access to it may have been possible though a space between the end walls of the two buildings. The smaller room faced the opposite way, the same direction as the hall; but it also opened on Structures Q-166 and Q-167, small outbuildings associated with the residence. Since the residence formed a broken T with the end of Structure Q-165, this back door also gave access to one end of the residence.

The main room of Structure Q-165, facing the small court, was of rectangular plan, with two L-shaped benches meeting at the rear center at an altar. The roof, undoubtedly beam and mortar, to judge by the depth of debris and the high plaster content, was supported in the center by four columns, two in the doorway and two, more widely spaced, on the longitudinal axis. The masonry was fairly good, in contrast to that of the other room.

In front of the altar was an ossuary cist containing five burials, two figurines, and a pottery jar. Despite a relative lack of incensario sherds, the altar and ossuary cist argue for this room's being considered a shrine, which, because of the direction it faced, probably served the residence Q-168. Since there was not room in the cist for five complete bodies at once, and since some of the bones were articulated and others were disturbed, it seems likely that the cist served as a family vault and was in some way connected with ancestor worship, the bodies being placed there at death, so that there was time between burials for decomposition to take place.

The adjacent room opening to the rear of the structure was built of very inferior masonry. The floors were almost entirely missing; just enough remained to establish a top floor, level with that of the main room, and a lower one, in places just above bedrock. To judge from the ashy soil, type of refuse, and quantity and type of artifacts, the room served as a kitchen or workshop during at least one period of its existence. Just above bedrock were found three burials which apparently are to be associated with the upper floor.

In the center of the room a narrow natural opening, which had been artificially widened, led down to

a small natural cave. The opening had been plastered around the mouth and covered with several slabs of stone. Within the cave were three burials and a bowl, broken but with large pieces in position, containing charred human and animal bone and ash, presumably representing a cremation. A pot lid from very near by may have covered it, though the fit was poor. Grave goods were almost completely lacking in all burials.

Structure Q-165 seems to have served the dual purpose of shrine and kitchen. The shrine appears to be associated with the residence Q-168. The kitchen, facing the outbuilding at one end of Q-168, could have served as the kitchen for this house or could possibly have been used for the ritual preparation of food for the colonnaded hall. Chowning suggests that Structures Q-166 and Q-167 may have been kitchens. If this is so, then the probability of association with the hall is increased. The doorway between the kitchen of Q-165 and the shrine room suggests religious use of the former, possibly for the serving of food to persons secluded in the shrine during a period of special diet and continence. It is possible, then, that the group as a whole answered the demands of the colonnaded hall, the shrine serving the residence and the attached kitchen serving the hall and the members of the household secluded in the shrine. If Q-166 and Q-167 were for culinary use, this would presumably be to prepare the daily food of the occupants of Q-168.

40.32.

ANN CHOWNING

Excavations at Mayapán

YB 54: 276–277, 1955

Late in the season Chowning excavated three connected house mounds in the Main Group, Structures Q-166, Q-167, and Q-168. They seem to belong to an assemblage which also contains a colonnaded hall, Q-164, and Structure Q-165, excavated by D. E. Thompson. The three structures in question stand on a single L-shaped platform, with the principal house, Q-168, forming the shank of the L and facing southeast. Like Structure Q-165, which is parallel to the short arm of the L and almost touches it, Q-168 faces a small built up area, supported by a terrace wall which runs from the east corner of the building platform and seems

to contain a staircase leading to the group. The house platform is interrupted in front of Q-168 by what may be the entrance to the house. Two lines of large stones set on end, the front line lower than the rear, run across the front of the house. The side and back walls are low, and the lack of surface debris indicates that the upper part of the house was composed of perishable materials. There are three benches, one of them L-shaped, in the front room, medial walls behind each passageways between them, and two benches in the back room. There is no sign of an altar, nor any indication that ceremonial activity was carried on in the building, though fragments of three human figurines and of effigy incensarios were found in the fill of the benches. One of the rear benches completely fills the space between the medial and back walls, but the other is set against the back wall, and next to it is a passageway to an end room, which is cut off by a wall running the length of the L-shaped front bench. This room contains benches in two corners; and another construction partly within the room but extending beyond the back wall; presumably it is an exterior bench. A doorway in the side wall leads to Structure Q-167. Excavation within the passageways and benches of Q-168 revealed no burial crypts, but fragments of human bones were scattered in the fill in front of one of the front benches, and the skeleton of a child, accompanied by bone and shell ornaments, bone awls, and an obsidian arrowhead, was found under a bench in the end room. A broken metate, several manos, including part of one of which the remainder was found in Structure Q-165, and heavy concentrations of coarse household ware indicate that this was a simple dwelling, like many others in Mayapán, in which domestic activities were performed.

The plan of Structure Q-167 is not nearly so clear, and it is difficult to say whether, in fact, one structure or more than one is represented. It fills the angle of the L, and contains an L-shaped bench behind which is a wall that continues as the terrace wall of the short leg of the platform. The orientation of the bench and the wall indicates that this structure faced southwest, away from the plaza, and a break in a low wall in front of the bench may be the doorway. Another narrow bench connects this one with a larger bench which was built against the side wall of Structure Q-168, and in front of the connecting bench is a square bench which is independent of any wall. The floors in this part of the structure are considerably higher than those in front of the L-shaped bench. Attempts to find a wall around the part of the structure adjacent to Q-168 failed. The fill of this structure is true midden debris, full of ash, animal bones, and the sherds of household pottery, and it seems likely that a kitchen, possibly that of Q-168, is represented by at least a part of the construction.

Similar midden debris is piled against all the terrace walls in this group.

Structure Q-166 occupies the end of the L, and is separated by a narrow strip of plaza floor and bedrock from Q-165. It has a clear back wall, a single bench with a medial wall behind it, and a narrow passageway and side exit behind the bench. It again faces the plaza, and the unwallled platform seems to have functioned as the front part of the structure. It stands on a higher level than the adjacent parts of Q-167, and there is no sign of a doorway between the two. The use of Q-166, is conjectural, but the debris within and around it is like that of Q-167, and it probably was part of the same domestic assemblage. A pair of terrace walls runs behind both these structures. A few fragments of effigy incensarios and a figurine head are the only indications of religious life, and both are often found in simple households. The proximity of the three structures to Q-165 indicates that they are connected with it, and perhaps with the colonnaded hall Q-164, but the nature of the constructions and the artifacts within them makes it evident that the role of those who lived and worked here was a subsidiary one, possibly that of servants to the occupants of the more important structures of the group.

40.33.

H.E.D. POLLOCK

Excavations at Mayapán

YB 54: 278–280, 1955

In 1954 a series of test excavations were carried out by Pollock at the northern terminus of the principal *sacbé*, or artificial road, at Mayapán [Chapter 40.34 this volume]. This work was done with the intention of determining the time of construction of the *sacbé* in relation to the architectural assemblage at its northern end and, so far as possible, in relation to the span of occupation of the city. Somewhat surprisingly, it developed that the road was a relatively late construction.

During the field season covered by this report, similar, but slightly more extensive, operations were instituted at the southern end of the *sacbé* where it terminates at the somewhat smaller assemblage of buildings known as Group Z-50. The time of construction of the road was checked, as had been done at the northern end, and in addition Group Z-50 was mapped and limited excavations were made that led to some, but by

no means complete, understanding of the growth and nature of the complex.

Group Z-50 is a raised courtyard enclosed by buildings on the east, south, and west, and entered from the north, where a stairway rises from the surface of the *sacbé* to court level. Near the center of the court are several low platforms suggestive of altars, and a stone of the sort that is thought to have been used for human sacrifice. A simple geometric design runs around the stone. A short distance west of the *sacbé* a subsidiary stairway rises from ground level to the northwest corner of the courtyard, and two other stairways, also rising from ground level, are on the east side of the group. Between them, built into the main platform, is a small room entered from ground level. The ceiling of this room, which had been roofed by beam and mortar construction, must have been about on the level of the surface of the main platform, which here forms the eastern terrace of Structure Z-50a.

Structure Z-50a, the eastern building, consists of two rooms separated by a medial wall with a centrally placed doorway. Each room is entered by a two-column doorway, the one facing east, the other west on the courtyard, and by doorways at each end of each room. Two benches are built along the medial wall in the west room; there is one in the east room. To judge from the depth and character of debris, the roof was of perishable materials, presumably thatch, although the stone walls must have risen to considerable height. This is a type of structure that is relatively rare at Mayapán. It is known to occur in groups of buildings that almost surely were domiciliary. The extraordinarily open plan of Structure Z-50a with entrance from all sides, however, does not suggest the privacy one expects in the typical family residence. At present we are uncertain of the function of this type of structure. It is entirely possible it was for dwelling purposes although not the residence of a family.

Structure Z-50b, the southern building, faces north on the court, where it is entered through a wide two-column doorway. The large front room has a single bench in its southwest corner and a centrally placed doorway in its rear wall that leads to a narrow chamber, without other entrance, occupying the southwest corner of the building. Against the back wall of this room and the back wall of the building, just opposite the doorway, is what we take to be an altar rather than a bench, because of its central location and narrow proportions. From the fill of this altar we removed a little tripod cup of a type commonly found in caches, and a jade bead that had undoubtedly once been inside the now broken cup. East of the front and rear rooms, running around the southeast corner of the building, is an L-shaped chamber entered by single-column doorways on the south and east and by a nar-

rower doorway on the north. This room does not communicate directly with either of the other rooms. A large bench, which blocks the southern half of the eastern doorway and part of the southern doorway, fills the center of the room from wall to wall. Against the east face of this bench, and outside the doorway, a smaller bench, added secondarily, rests on what was a secondary widening of the terrace of the building at that end. The latter bench is thus in the open, but it is entirely possible that this whole area had been covered by thatch, although the rest of the structure had carried a beam and mortar roof. Although Structure Z-50b is hardly typical of Mayapán dwellings, the bench and terrace arrangement at the east, which suggests kitchen appointments, leads one to suspect that this structure may have been used, at least in part, for domestic purposes. Debris of the nature of a kitchen midden was found in the corner between the south end of Structure Z-50a and the east end of Z-50b. This refuse may have come from either building.

Structure Z-50c, a long single-room building that lies along the west side of the group, is approached through a wide four column entrance facing on the court. Two benches and a centrally placed altar, in front of which were fragments of incense burners, run almost the entire length of the rear wall, ending just short of the north end of the room in order to allow passage through a doorway in the rear wall. This doorway and one in the north wall let onto a narrow terrace that runs along the back of the building and across the north end. At the south end of the room a doorway opens to a small courtyard or terrace between the ends of Structures Z-50b and Z-50c. The character of the debris in the room left no doubt that the building had carried a beam and mortar roof. At the north end the charcoal remains of a roof beam and the fire-blackened floor indicated that this part of the roof had burned. Oddly enough, similar signs of burning were not found at the middle of the room, the only other area cleared to floor surface. Structure Z-50c, in plan and interior arrangement, is rather similar to the colonnaded halls found in the main ceremonial center at Mayapán. There is reason to believe that such structures, although primarily ceremonial in nature, were lived in by certain groups a certain times. Structure Z-50c may well have seen similar use.

The previously mentioned area that lies south of Structure Z-50c and west of Z-50b carries the remains of the usual plaster flooring. In this floor, toward the eastern side of the area, is an opening into a roughly built chamber in the fill of the terrace that reaches bedrock and resembles a chultun or cistern. The chamber shows no indication, however, of ever having been watertight; indeed, the open fill that forms its sides and the creviced bedrock of the floor give quite the

opposite impression. The relatively meager amount of pottery, stone implements, and bones that came from the debris in the chamber also seems to rule out its use for the disposal of refuse. If by any chance, the Maya provided toilet facilities within their buildings, a practice that does not seem very likely, this opening might have served such purposes. No other construction was noted in this area. Although the terrace was only partly cleared, the debris was not deep and any walls of stone would presumably have been observed. If the area was roofed, or was walled at the south and west, such construction must have been of a perishable nature.

Our excavations in this group were limited, being designed primarily to date the *sacbé* and to obtain a plan of the architectural assemblage in its final stage. There nevertheless emerged some indications of building sequence and the growth of the complex. To judge by the joints between the plinths or building platforms supporting the three structures, Structure Z-50b was constructed, before Z-50a and Z-50c. Evidence involving the growth of the main platform of the group indicates that Z-50c was the last built. We also ascertained that the *sacbé* had once extended 7–8 m farther south to an old terrace wall buried by the subsequent northward extension of the main platform. There were the barest traces of what may have been a stairway at the earlier terminus of the *sacbé*. Lastly, there was some indication that the main platform had been extended westward to enable the building of Structure Z-50c.

The pottery from the fill of the *sacbé* checks the conclusion from our work of the previous season, namely, that the road is a late construction with reference to the occupation of the city. Indeed, the pottery from all our digging at this group suggests a late period. There seems to be one difference between the situation at the southern end of the road and that at the north. We know that some construction, *viz.*, the northward extension of the main platform, and possibly a western extension, was carried on at Group Z-50 after the completion of the *sacbé*. Indications, and it should be stressed they were no more than indications, at the other end of the road were that the *sacbé* may have been built when the architectural complex there had reached its final form.

The function of Group Z-50 in the life of the city is not so clearly marked as in the case of many other structures. It has been noted in preceding paragraphs that none of the buildings in the group are typically residential, in the sense of the family domicile. The sacrificial stone in the courtyard, if our identification of this form of monument is correct, is not the sort of object one might expect to find associated with the family dwelling. It should be remembered that Group Z-50 is connected by a relatively imposing roadway with a large assemblage of buildings that probably

was a residence of the nobility or aristocracy. One wonders if the road would lead from this residence merely to another group of dwellings. In spite of these indications that Group Z-50 was not a residence in the sense of the primary living quarters of a family or extended family group, the fact is that the nature of the pottery, and to a lesser extent the artifacts of other materials, that was recovered is just about what one might expect from habitations. Taking the evidence in hand, and it leaves much to be desired, it is probably best to think of this group of buildings at the southern end of the sacbé as being essentially ceremonial in nature but involving rituals that required residence during certain periods. One suspects, moreover, because of its connection with the imposing structures at the northern end of the road, that the use of Group Z-50 may have been restricted to the occupants of the other group.

40.34.

ANN CHOWNING

*Excavations in the Itzmal Ch'en
Ceremonial Group at Mayapán*

YB 54: 280–283, 1955

D. E. Thompson and Chowning spent much of the season investigating the small ceremonial group in Square H, next to Cenote Itzmal Ch'en. The group, which is located near the city wall in the thinly populated eastern part of Mayapán, consists of four large structures, H-14, H-15, H-16 and H-17, one on each side of a rectangular plaza, and a fifth structure, H-18, roughly in the middle of the plaza; a sixth one, H-12, lies outside the plaza proper, near the edge of the cenote. Four smaller associated constructions, H-13, H-16a, H-17a, and H-18a, presumably functioned as shrines. All these were excavated sufficiently to make their ground plans clear; only Structure H-18 and the shrines were investigated more thoroughly. Later, all the structures were included in a map of the group prepared by Proskouriakoff. Trenches were also run from H-18 to H-15, H-16, and H-17 in an attempt to determine the temporal relations of the buildings and to obtain stratified pottery samples.

The plaza of the group is on a natural rise in the limestone, which has been leveled in places by the addition of an artificial fill of stones. Supporting terrace walls run around the edge of the plaza, which is

approached by a staircase on the west side. In most parts of the plaza only two plaster floors are visible, though next to buildings the number sometimes rises to 5. No floor was complete enough to make it possible to establish the exact chronological relations of different parts of the group.

The main structure of the group, H-17, stands on the north side, and, like all the other structures, faces the plaza. The substructure is a pyramid with two terraces and a staircase which is inset at the top; the pyramid is surmounted by a small temple. The temple, resting on a plinth, has a two-column doorway facing south, two interior columns, and L-shaped benches. At the rear of the building is an altar probably supported by four crouching human Atlantean figures made of stone covered with painted stucco. The two central figures were still supporting a large slab, but the exact form of the altar top is uncertain. A crudely carved jade head was found in the floor under the altar, and incensario sherds, three stone turtles, and a stone jaguar lay near by. One of the interior columns was originally painted in bands of red, yellow, black, and blue-green, but this decoration was later covered by a layer of plain white plaster. An unknown excavator had dug a trench through the rear wall next to the altar. Incomplete walls and a column adjoining the west wall of the temple indicate that another structure once stood there. The present pyramid represents at least the third remodeling of the substructure.

At the base of the stairway is a complex shrine, H-17a. On one side of it is a low platform or bench, in front of which stand the sandaled feet of two large stucco figures, and between them, a large stone serpent head. Two similar heads lay a short distance away, and a stone of the type thought to have been used for human sacrifice is set in front of the figures. Another platform, of more irregular shape, extends to the west of the first one, and between it and the staircase were several pieces of sculpture, including a round "altar," a square one, and three carvings of serpents; any or all of them may have fallen from above. The exact plan of this part of the shrine is not clear. A stone "diving god" lay on the surface.

Directly south of Structure H-17 is a round building, H-18, which stands on a square platform with a balustraded stair case on each side. The temple has four doorways, oriented, like the stairs, to the cardinal directions. This fact is particularly interesting because this is the only round structure at Mayapán to have four doorways, and Landa reports a legend that such a building was constructed there. In the middle of the single room is a round pier, 1 m in diameter, built around an earlier central column and resting on a wide circular plinth. In the pier are four niches facing the doorways of the room, and in the west niche, which

seems to have been made to accommodate it, rested a well made round stone altar, under which one jade bead was found. It is impossible to say how much taller the pier, now almost 1 m high, formerly stood; presumably the central column, and conceivably the pier, helped support a beam and mortar roof. A stone monkey with tenons on its back lay in front of the south niche, and a turtle with badly weathered glyphs on its back was found beside the substructure. There were remarkably few incensario sherds inside the temple, though the floor showed signs of burning.

The present substructure encloses an earlier one which stood to the same height and also had four staircases, all but one of which were largely destroyed before rebuilding. No traces remained of any earlier superstructure. On the north side of the substructure a crypt was built, using a balustrade and wall of the earlier substructure, the wall of the later substructure, and a specially built end wall for its four sides. In this crypt, in a space roughly 1 m long, 50 cm wide and 1 m deep, were jammed the well-articulated skeletons of 14 adults. There were no grave goods except a large conch shell at the bottom of the crypt. The bodies were of both sexes, showed a considerable age range, and obviously were put in at different times. The skulls of two were missing. The unceremonious manner of burial and the proximity of the crypt to the sacrificial stone in front of Structure H-17 suggest that the skeletons represent the victims of the rites thought to have been performed there.

Southwest of Structure H-18 is a small construction designated as H-18a. It is built directly on the plaza floor and has three parts. One is a low platform in front of which are the remains of two pairs of stone and stucco feet. The scattered parts of the rest of one of the figures, including both hands holding flattened balls, lay in front of the feet; the other figure seems to have been destroyed earlier just west of this one is a much cruder platform or bench. To the south of these constructions, and hiding one of the pairs of feet, is a low-walled, three-sided enclosure, the open end to the west, surrounding the upper half of a large stucco figure which lay on the plaza floor. The rest of the 1.3 m figure was unprotected, and if the walls ever bore a superstructure, it was of perishable materials. The figure wears a garment resembling feathers, and elaborate wrist and ankle ornaments. Its arms and legs are spread so that the elbows and knees form right angles, and on these joints are death's heads, like those depicted on the joints of the Aztec "earth monster." The hands and head of the figure are missing, but scattered plumes may represent part of a headdress. This figure lies over a similar smaller one which was carved in high relief on a single block of stone almost 1 m long. The stone figure also has skulls on its joints, and

serpent heads of classic Maya type were carved in low relief between the arms and legs. Large round holes which pierce the stone represent the eyes and presumably had a functional use; they were the only part of the stone visible under the later stucco covering. The bodies of the serpents cross at the end of the stone, and each tail ends in three rattles. Fragments of effigy incensarios lay between the legs of the stucco figure; the legs, like the arms, extended well beyond the stone and were modeled over small unshaped rocks. Four shell and two jade beads were lying beside the figure, two burnt jade beads were in a broken incensario buried between the legs, and two more jade beads and a fragment of copper lay under the carved stone. It is impossible to say what deity was represented, but the combination of Maya and Mexican motifs is particularly interesting, especially since this figure was in use at the time of the abandonment of the city.

Of the other structures in the group, H-12, H-15, and H-16 are typical Mayapán colonnaded halls, each with two rows of columns, back and side benches, an altar in the rear, and a beam and mortar roof. In all three, there were heavy concentrations of incensario sherds in front of the altars. Only H-12 has attached to it a house (H-11), which seems to represent the building usually associated with colonnaded halls, presumably to provide service. This hall differs from the others in not being approached by a staircase; together with H-11, it stands on a separate knoll or terrace outside the plaza. Like H-15, it has a single transverse room, apparently a late addition. One of its columns is replaced by a rectangular pier. Structure H-15, the largest of the three, is approached by a very wide staircase with massive balustrades. Its transverse room is almost completely filled by a bench. A number of stones carved with designs of the Puuc period were scattered at one end of the main room, and in front lay a stone carved to resemble a sacrificial stone borne on the back of a crouching animal. It apparently was not in place. The third colonnaded hall, H-16, is badly destroyed, partly as the result of the removal of stones both before and after the fall of the roof. It was possible to ascertain that it had undergone extensive remodeling, probably more than once. Both the back row of columns and the rear benches had been moved forward. In the latest period, the benches in the main room were faced with plain and decorated stones of Puuc type, so arranged as to form a simple design. There was a transverse room at each end, and the south one was approached by its own staircase. This latter room seems to have had a thatched roof, though the rest of the hall had a beam and mortar roof, and the presence of metates and plain coarse ware in this room may indicate that some of the household activities often confined to a separate structure were performed here. Exploration

in the altar, of this building and in that of Structure H-12 failed to reveal any signs of a cache, but in both cases breaks in the plaster tops of the altars may indicate looting. In front of the south room, on the level of the plaza floor, a tiny three-sided structure, H-16a, faced west. It contained only two low stone and plaster steps, but the broken parts of a grotesque stone figure found near by may indicate that the shrine once held an idol. A round altar lay on the ground beside the shrine. There were no offerings in evidence.

The other major building, H-14, lies on the west side of the plaza. Like all the structures in the central group, it has its own platform, but in this case the platform is so low that no stairs were necessary. The building, which shows signs of remodeling, is similar in plan to Structure H-17. It has a triple doorway formed by two columns and jambs, two interior columns, and back and side benches. The building is in such a state of disrepair that it is impossible to ascertain if there was an altar in the rear; there was no particular concentration of incensario sherds in the building. Fragments of human bone were found outside it.

Little is left of the remaining structure, H-13, but its square platform; and the scantiness of the debris indicates that if a building ever stood on top, it was made of perishable materials. The small structure stands at an angle in the northwest corner of the plaza and has a balustraded staircase on its southeast side. Off center in the platform, and set at an angle to the platform, a narrow rectangular shaft reaches down 2 m. It contained the badly scattered and decayed bones of at least three adults and one child. Again there were no grave goods. There were indications that a niche on the stairs may once have held a stucco figure.

Itzmal Ch'en seems to have been a secondary and minor center of worship at Mayapán. The fact that the annual rain ceremony of Telchaquillo is still performed at this cenote may indicate the nature of this worship. In addition to its smallness and the apparent lack of much rebuilding and remodeling, Itzmal Ch'en differs from the Main Group in that there is no indication of the burning of buildings and no positive evidence for looting of caches, whereas the beads on the surface of Structure H-18a seem to show that it was not looted. The destruction of the statuary may or may not have been deliberate. Both Structures H-16 and H-17 have certainly been dug in, but it is impossible to say when or by whom. In types of structures and artifacts, such as stone turtles and effigy incensarios, Itzmal Ch'en does not differ from the Main Group, and it is possible that it escaped depredation, if indeed it did simply because of remoteness. As elsewhere in Mayapán, there is extensive re-use of stones, seemingly of the Puuc Period, but no sign of the buildings to, which they once belonged.

EDWIN M. SHOOK

Excavations at Mayapán

YB 54:283–284, 1955

A period, of two weeks was spent at Mayapán during the 1955 field season investigating a small round temple, Structure Q-126. This unit, the best preserved of the four round temples at Mayapán, was selected for repair and solidification. The latter, work was carried out by Strömsvik.

Structure Q-126 is situated on the eastern periphery of the concentrated ceremonial group of structures, surrounding the Temple of Kukulcan or Castillo (Structure Q-162), and lies on the north edge of what appears to be the main avenue of approach from the east to the heart of the city. As with the majority of buildings in Mayapán, only a few architectural features were discernible above the fallen mass of rough stone. The partly exposed western walls of the platform and temple provided the initial knowledge that a round building rested on a raised rectangular platform. The excavations included the complete clearing of the temple, the exposure of the west and south sides of the substructure, and minor trenching into the latter for earlier structural phases. The trenching disclosed three plaza floors and a small rectangular temple or shrine predating the round temple, but still built within the Mayapán Period. This earlier building and the floors were later buried by the relatively high substructural platform of the round temple. A broad stairway, flanked by plain ramp-type balustrades, on the south side of the platform gave access to the frontal terrace of the temple. Here evidently stood a line of plain and carved stelae before the temple doorway. Fragments of two plain stelae remained on the terrace, and both plain and sculptured monuments lay at the southern base of the platform, seemingly fallen from the terrace. The temple is a duplicate in plan of Structure Q-214, previously reported [Chapter 40.21 this volume], with a round outer wall enclosing a space divided in half by a medial partition. A single doorway on the south provides access to the first small chamber, another in the medial wall gives entrance to the rear room. The temple's lime concrete floor showed heavy staining from considerable burning, concentrated on a north-south line from the outer doorway and increasing toward the rear chamber. In addition, a layer up to 15 cm thick of ashes and charcoal mingled with pottery censer fragments covered the floor. Against the rear wall, opposite the doorway, an irregular, circular patch where the floor was missing marked an area heaped

with ashes, charcoal, and censer fragments. If a masonry altar once stood against the rear wall, it had been ripped out before the heavy burning which took place in the back room.

The evidence of incense burning within the temple, the accumulation of pottery censer fragments around the base of the substructure (apparently sweepings from the temple and terrace), the secondary addition in the center of the substructure stairway of a tiny shrine room containing a modeled stucco idol, and the many associated stelae, all point to the importance of Structure Q-126 as a temple for ceremonial rites. The striking similarity of Structures Q-126 and Q-214, in all but minor details, suggests that the two temples served identical functions. The fact that one faces south, the other east almost certainly precludes their use for astronomical purposes.

The pottery recovered from Structure Q-126, from the excavations by Chowning and D. E. Thompson, in the ceremonial group at Itzmal Ch'en, and from the digging in Group Z-50 by Pollock was analyzed by Shook during the past season. The major portion of his time was devoted to the general study of the pottery of Mayapán for a forthcoming report.

40.36.

GUSTAV STRÖMSVIK

*Exploration and Reconstruction in
Mayapán and Vicinity*

YB 54:284–285, 1955

During the first part of the field season Strömsvik assisted Chowning and D. E. Thompson in their digging for building plans and architectural details at Itzmal Ch'en. The results of these excavations are reported by Chowning.

In conformity with our policy of consolidating certain representative buildings at Mayapán, Shook cleared the round structure Q-126, 200 m east of the Castillo, at the beginning of the season. Early in March the consolidation of the rectangular substructure was started. The entire west side was taken down, to be relaid in lime mortar, except for a section at the north end, where a joint between this and an earlier structure was plainly visible. Good lime-mixed mortar was still there between the stones, and the wall was undoubtedly as straight as the ancient builders had left it. In this section the cracks were filled with cement

and chinking, without moving the stones. At the south side, the stairway was partly rebuilt as high as the sixth step, and the balustrade stones were reset as far as they were found. Also, a small shrine in the middle of the stairway was solidified to the extent that it was found. In examining the round building on top, it was discovered that the wall contained much of the original mortar. Only the outer facing of this part of the construction was reset in fresh mortar; the cracks between the stones in the inner facing were chinked with mortar without taking the wall down. The inner door-jambs were reset to the height found when they were excavated, as were also the outer door jambs. The tops of the walls and the cracks in floors and stairs were sealed with rich cement mortar. A small, broken stela was repaired and set upright on the west side of the substructure, and at the east side a small, much damaged stela with faint traces of hieroglyphs was laid leaning against the rubble on the unexcavated east side of the substructure.

In addition to this work of repair at Structure Q-126, it was planned to solidify the existing remains of a city gate and a section of the city wall to give an impression of how the Great Wall of Mayapán had once looked. Gate D, 400 m east of the Telchaquillo-Tekit road, was chosen as a good example. This gate had been partly excavated in 1952 (Shook 1952:10–12). A stretch of wall just west of the Telchaquillo-Tekit road was thought to be both representative and easily accessible to visitors, and this section was restored to its original height, with a plaster floor on the banquette, according to the evidence found. By the end of May all work of consolidation was finished.

Some months earlier natives of Telchaquillo had told Strömsvik about a cave near the town of Tecoh, about 10 km north of Mayapán, called *Dzab-Na* (House of Rattles), where, according to legend, the remnants of the Mayapán people took refuge when their city was destroyed. This cave seemed worthy of investigation, and in June this was undertaken. Using a small lighting plant and all available electric cable, the center area, about 100 m in diameter, was investigated and mapped. Three cenotes were seen in the cave, but the natives say there are 7. A good quantity of potsherds was found, but no stratigraphy, there being no depth of soil. Even so, one can say that the cave floor was strewn with typical Mayapán wares, underneath which were found quantities of Slateware. Fragments of classic Maya polychrome were also seen. A discovery of particular interest was a statuette of polished black wood. The seated human figure about 15 cm high, is remarkably well preserved. Articles of perishable materials are of course extremely rare, and any such finds come as more than welcome additions to our knowledge of the ancient arts and crafts.

40.37.

ROBERT E. SMITH

Pottery of Mayapán and Vicinity

YB 54:285–286, 1955

The number of potsherds collected at Mayapán during the 1955 field season approached 200,000. This collection amplified rather than changed the picture as shown in last year's report. A few results, however, are significant. Effigy-type incense burners were more than twice as abundant in and around ceremonial structures as they were in association with dwellings, whether the dwellings were of elaborate or simple type. The smaller number of incense burners found with house mounds was offset by the increase in Mayapán Red and Porous Gray wares. Mayapán Red on Buff or Red and Black on Buff pottery, never found in large percentages, was three times as abundant in house mounds as in ceremonial structures. Black on Cream Ware was twice as abundant in ceremonial structures as in the more elaborate dwellings; the ordinary house mound rarely harbored any Black on Cream sherds. There is still much to be learned from a careful study of the pottery associated with different types of structure, and even of the pottery from functionally different rooms within structures.

The pre-Mayapán Period material found at Mayapán amounted to less than one percent. It was outside the city that early potsherds abounded. In a survey of small outlying sites, usually close to cenotes, sherds were picked up within the cenotes as well as from the surface outside. This collection totaled nearly 3,000 pieces, of which 42.2 percent were of Puuc or lowland Maya Classic type and 1.1 percent were Preclassic. Many of these sites had colonial sherds (12.4 percent). Actually, save for a few fragments of effigy incense burners and even fewer Mayapán Red on Buff sherds, the Mayapán Period was poorly represented.

40.38.

WILLIAM T. SANDERS

Explorations on the East Coast of Yucatán

YB 54:286–289, 1955

This season Sanders continued his ceramic survey of the east coast of Yucatán. The previous field season

had been spent in a general survey of the coast from Holbox to Tulúm, and included small test excavations for ceramic samples at 37 sites. The pottery indicated a great abundance of sites of the Mayapán Period and a few sites of the Classic Period. This year it was decided to concentrate on two major sites, Tulúm and Tancah, within the area mentioned. These were selected as important centers for the Mayapán and Classic Periods, respectively, and it was hoped that extensive testing at both would enable us to break down each period into phases. Aside from ceramic differences, the two sites show important distinctions in architectural style, and by ceramic testing it was thought that some idea of the development of the East Coast architectural style might be attained.

A crew of workers was brought from Kantunilkin to Tulúm to carry on the excavations, labor being completely lacking in the latter area. A total of three weeks was spent at Tulúm, and over 40 trenches were excavated in and around all the major buildings. In general these were dug along the edges of temple and palace platforms, usually in the vicinity of stairways. A few trenches were excavated in buildings, mainly involving small platforms rather than major structures. Several rooms were cleared of roof and wall debris to get above-floor samples.

The average depth of soil and cultural deposit at Tulúm is very shallow, the deeper deposits, 50–100 cm, occurring in and around Main Street, which crosses the city from the west gate in the north wall to the west gate in the south wall. On the rocky knolls which underlie the Inner Enclosure, Cenote House, Temples 45 and 54, and slopes in general, sherds are often found on bare rock, and at most the soil depth runs from 10 to 30 cm. In spite of these conditions, excellent sherd samples were obtained in the vicinity of all major structures. The trenches indicate clearly, by the absence of extensive floor construction, rebuilding, and gross depth of cultural deposit, that the period of occupation at Tulúm was extremely short, probably not exceeding a few centuries.

Six weeks were spent at the site of Tancah. Here the situation was quite different. Excavations were conducted in Groups A and B, with those in the former yielding best results. Excavations in Plaza A revealed a complex succession of paved floors running from three to seven in number, and samples of pottery were obtained from a number of these levels. On top of the first floor and in the top soil layer, typical Tulúm Period censer wares were found, but all the pottery below floor levels is Classic in date. Extensive trenching in the vicinity of the two major groups indicated an over-all soil-refuse depth of approximately 50–100 cm, with several trenches running to 2 m. Very little Tulúm pottery was picked up in these trenches, a fact which

indicates that the Tulúm Period occupation of the site was ceremonial in nature. Lothrop's site map was considerably extended, and the new structures added, mainly platforms and a few temples, are at least equal in number to those mapped by him. Ceramic samples were also obtained from the platforms of the newly mapped temples.

On completion of the work at Tancah, operations were moved to the Chetumal area, where two weeks were spent testing two sites, the walled site of Ichpaatún, which is of the Mayapán-Tulúm Period, and the Classic site of Calderitas. Both have been reported and described by Escalona Ramos. Excellent ceramic samples were obtained from each site, especially the former.

Preliminary analysis of the ceramic material indicates the following important points. Tulúm is the largest Postclassic site seen during the two seasons spent on the East Coast; it seems to be entirely of the Mayapán Period. There are four basic local wares. First, there is a Red Slipped Ware, which in general is very close to Mayapán Red Ware, although with finer paste and better surface finish. It occurs in three definite forms: tripod plates or bowls, tripod *molcajetes* or chile grinder, bowls, and jars, all three shapes showing close linkage with those at Mayapán. Secondly, there are several types of censer wares, at least two of which are exact duplicates in form of Mayapán censers. Thirdly, there is an unslipped ware running entirely to jars which show a close resemblance in lip and neck form to their Mayapán counterparts. The fourth ware, found in very small quantities, is the northern Yucatán Black on Cream. Fine Orange occurs as a light but consistent component and seems to be entirely of Berlin's Talmulté type. No Plumbate was found.

There appears to be slight possibility of breaking down our Tulúm Period into phases; it seems to represent a short period ceramically. Spatially, Tulúm pottery has a considerable range, especially the red and censer wares. Both occur along the coast from Holbox to Tulúm, and the pottery from Ichpaatún in the Chetumal area is almost a duplicate of Tulúm pottery. Good representative sites other than Tulúm are Cancun Island, El Meco, Chiquilá (Period 2), and San Gervasio on Cozumel Island.

The Classic Period along the East Coast is not so easily defined. There seems to be fairly good evidence allowing a breakdown into an Early Classic stage with strong Petén influences (Tzakol), followed by a cessation of Petén influence in favor of that from the Puuc region. The pottery from Tancah should help toward clarifying this problem. The above, statements refer strictly to the Holbox-to-Tulúm region, the situation, in the Chetumal area probably being quite different.

One interesting problem is the representation of the Early Postclassic or Toltec-Chichén Itzá Period on the East Coast. A number of sites excavated last season seem to fall in that time period in part, although lacking the diagnostic ceramic and architectural manifestations found at Chichén Itzá. The period seems to be characterized on the East Coast by a continuation of the Puuc Slate Ware tradition, with the addition of a distinctive local ware called by Sanders Vista Alegre Striated, after the site where it occurs in heaviest concentration.

Aside from study of ceramic stratigraphy, extensive testing, including mapping and excavation, was carried out at Tulúm and Tancah to obtain data on settlement patterns.

At Tancah, trails were cut at 20 to 40 m intervals, forming a grid pattern covering an area 540 m north-south by 600 m east-west and extending in all directions around the two mapped plazas. A careful search was made of all squares to map structures, whether religious or domiciliary in character. Secondly, trenches were excavated at most of the intersections of the grid trails to get an idea of the depth and quantity of habitation refuse and its distribution over the site. These trenches were all of uniform surface area (1 m by 1.5 m) and were carried to bedrock. Some 180 trenches were dug, and they gave an excellent idea of population distribution. A preliminary study of the data indicates the following conclusions: 1. There are few heavy refuse deposits anywhere at the site. Good deposits almost invariably occur just off temple platforms or house mounds. There are large areas of little to no cultural deposition between plazas or house mound clusters. 2. It seems almost certain that a good estimate of the population maximum of the site may be obtained on the basis of the house mound count alone. 3. The site is curiously overbalanced; there are as many buildings of purely religious function as there are domiciliary platforms, and the total of house mounds does not exceed a few dozen. 4. Almost all the house platforms are very large, often running 40–50 m in length, and are quite obviously not remains of dwellings of a proletariat. 5. We seem to have at Tancah an important religious center with a small resident elite population, probably not exceeding a few hundred persons, in other words a typical ceremonial center as, described by Torquemada for the lowland areas of Mesoamerica in general. 6. In the interior for a distance of several kilometers there are scattered through the forest small groups, each consisting of a small pyramid or two surrounded by six to 12 house platforms; apparently these were small agricultural hamlets of the type mentioned by Gaspar Antonio Chi in *Relaciones de Yucatán*.

At Tulúm the situation seems to be quite different. In spite of the lack of soil and much shorter period of

occupation, Tulúm has much more cultural refuse in general, and many more good ceramic dumps. The area enclosed within the main wall is approximately 450 m north-south by 200 m east-west, or approximately nine hectares or 22 acres [0.09 sq km]. Of this total, approximately three hectares are occupied by purely religious structures or by large palaces. The rest of the enclosed space, that lying west of Main Street and the section east of Main Street which lies south of the Inner Enclosure, shows abundant surface indications of a dense nucleated population. The area lying south of the Inner Enclosure and east of Main Street is sharply sloping, and the slopes are worked into a series of terraces to provide locations for dwellings. House mounds are rare, the population evidently having lived in pole and thatch dwellings directly on the terraces of the slopes, or directly on bedrock in more level areas. Approximately 70 trenches of the type excavated at Tanchah were made here. The results of these excavations checked the conclusions reached on the basis of surface remains. The indications are that we have a settlement pattern similar to that found at highland Mexican sites, an interesting fact in view of the strong highland Mexican influence in architecture and pottery at the site. One is, however, surprised at the small area urbanized, considering the number of religious structures and the importance of the site. The reason lies undoubtedly in the deficiencies of slash and burn agriculture as an economic basis for true urban society.

The entire area enclosed by the southern extension of the west wall is notable for the almost complete absence of refuse deposits and structures. It probably served as a refuge for the surrounding farming population in times of attack. Outside the walled areas there is no evidence of urbanization. An interesting discovery was made in the survey of the area south of the site. The forest just south of the walled area is crisscrossed by an amazingly complex system of defensive works, involving intersecting walls, double walls, and walls with parapets, which runs into the bush for hundreds of meters. Unfortunately, time did not permit mapping, a task which should be done within a few years, as the walls are in an advanced state of destruction.

40.39.

ROBERT E. SMITH

Ceramic studies in Yucatán

YB 55: 338–339, 1956

During the past field season Smith's work encompassed three main ceramic projects: a study of the surface material from Mayapán; the analysis of pottery from a number of test trenches dug by Strömsvik at Uxmal and Kabah; and a review of three wares (X Fine Orange, Tohil Plumbate, and Petén-like Polychrome) well represented in the Alberto Márquez Collection in Mérida. In addition, ceramic summaries of the pottery from Dzab-Na and from Xcaret were made, respectively, for Strömsvik and for E. Wylls Andrews.

The principal wares and forms found on the surface at Mayapán are representative of the latest ceramic phase at the site. They may be divided into six main wares: Unslipped Porous Gray or Cinnamon, Slipped Mayapán Red, Mayapán Red and Buff, Mayapán Red on Buff or Orange, Mayapán Red and Black on Buff or Orange, and V Fine Orange. The unslipped forms include low-necked, wide-mouthed jars with lightly striated bodies; huge high necked, bolster-rim jars, usually thickly coated with plaster; censers of three types, namely, effigy, ladle, and jar shapes, either tripod or with pedestal bases; effigy vessels in the form of turtles, humans or gods, and, frogs; figurines; and some bowls and dishes. The effigy and jar censers, effigy vessels, and figurines are usually painted, and most have appliquéd adornos. The slipped forms include jars, both water and storage; tripod dishes and bowls; flat-based bowls, both open-mouthed and restricted; basins with bolster rims and horizontal strap handles; and in the case of V Fine Orange (Berlin 1956), tripod basal-flanged bowls or dishes. The use of feet in the latest Mayapán phase (as well as in all earlier Mayapán phases) is prolific. Such supports, three, never 4, in number, are associated with nearly all forms, even, though rarely, with jars. The pottery, both slipped and unslipped, is closely comparable to the latest pre-conquest material found on the east coast of the Yucatán peninsula.

In the eight trenches dug at Uxmal, the pottery recovered amounted to about 25,000 sherds. All were reviewed rapidly, and about 14,000 were actually studied, material from the three best-stratified trenches, comprising 14 cuts in all, being used. All the pottery examined appears to be late in the Puuc sequence. There are six main wares: Unslipped Light Brown, Medium Slate, Thin Slate, Puuc Red, Holactún Slate, and Z Fine Orange. The principal forms associated with the

unslipped ware are coarsely striated jars and spiked censers with flange and pedestal bases. Medium Slate forms are water jars, bolster rim basins with vertical strap handles, flaring- or out curving-sided dishes, and incurved-rim ring-stand bowls. Thin Slate forms, which differ somewhat from Medium Slate, are round-sided bowls with direct or bead rim (often with three nubbin feet), cylinder vases with flat or pedestal bases, restricted orifice bowls, flaring- or out curving-sided tripod dishes, deep bowls, and basins. Puuc Red shapes, much the same as those of Thin Slate, are round-sided bowls with, direct or bead rim, (rarely with pedestal or three hollow oven feet), flaring or outcurving-sided tripod dishes, cylindrical vases, and flaring-sided bowls rounding to flat base (mostly with moldmade carving). Holactún Black on Cream Ware has very distinct forms, including bolster or thickened-rim jars, T-bolster rim basins, and incurved and bolster rim bowls.

The ceramic picture at Kabah, as shown by our findings, differs from that at Uxmal in that there is evidence of a sequence comprising an early and a late phase, and possibly a middle phase. Z Fine Orange and Holactún Black on Cream are found in the upper and middle levels but not at the bottom, where a small quantity of Petén-like Early Classic polychrome types occurs. Many other differences between the Kabah and Uxmal material will be presented in a later publication.

The recording of the X Fine Orange, Plumbate, and Petén-like Polychrome wares from, the Marquez collection is important, even though precise data as to the circumstances under which the pieces were discovered are lacking. As the specimens are recognized ceramic types, they add to the body of information regarding those types. This is particularly true of, categories of pottery that are known only in the form of sherds, whole pieces such as these shedding light on vessel shapes and systems of decoration. Finally, it is always well to make record of material in private hands, for not only is this often difficult of access to students, but also there is danger that it may become scattered and lost to science.

A few words will suffice for the material from Dzab-Na and Xcaret, since the work done at these sites is being published by the respective excavators. Dzab-Na is a cave and cenote located near the town of Tecoh. The pottery collected in the Pave was not stratigraphically separated but was removed as a unit. It consists of Preclassic, Puuc and Petén-like Classic, and Mayapán Period pottery, in that order of importance. Xcaret is a large site on the east coast of the Yucatán peninsula, opposite the northern extremity of Cozumel Island. Ceramically, Xcaret appears to be primarily of Puuc type: although Mayapán Period and even recent types, as well as Petén-like, polychromes and a few

Preclassic specimens, are present, the great majority, of sherds belong to the Puuc tradition.

40.40.

TATIANA PROSKOURIAKOFF
Artifacts of Mayapán

YB 55: 339–341, 1956

Archaeological work in recent years has been centered largely on architecture settlement patterns, and pottery collections. Stone tools and other small artifacts that would throw light on, the technologies of the peoples concerned have received very little study. Only major excavation projects yield collections of a size that can provide an adequate sample of tools used by a given people. Comparison and even description of the technologies of various Middle American cultures still await necessary reports of relevant data. Such reports are available for only a very few sites in the Maya area and are completely lacking for most of Mexico. A. V. Kidder's studies of the artifacts of Uaxactún and of Kaminaljuyú, and Woodbury's description of those from Zaculeu, give us information on the tools used by the Maya during the Classic period in the Petén and in the highlands. The collection from Mayapán will extend our knowledge to the Postclassic period in Yucatán.

Unfortunately, literature is particularly deficient in data that would acquaint us with locally antecedent techniques, but the Institution's unpublished catalogue of objects from Chichén Itzá, and scattered pieces in museum collections, provide some background for judging the effect of the violent events of the Postclassic era on the material culture and resources of the people of Mayapán. The present study, however, remains primarily descriptive, and is concerned not so much with the history of particular techniques or the tracing of trade relations as with the total complex of tools and ornaments characterizing a particular stage of Maya culture. For this purpose, technical identification of the material of every specimen, although highly desirable, was not deemed essential, and expert advice was sought only on selected samples. Metal was the only exception; the entire collection of metallic specimens was brought to the United States for analysis, and Dr. William C. Root, of Bowdoin College, is now examining

it both for composition and for working technique. Mr. Robert Berman has given us help with the identification of samples of stone imported to Mayapán from other regions, and Dr. W. J. Clench, of Harvard University, has examined and identified varieties of shell. In addition, Miss Joy Mahler has helped us with descriptions of fragments of textiles, and Mr. Clayton Ray with animal bones used for artifacts.

Although the study has barely passed its initial stages, a general view brings out interesting contrasts with other known collections. For example, highly specialized forms of large stone tools found at Mayapán are comparable to those at other sites, but the number of roughly shaped tools used in stone working and plaster smoothing far exceeds what has been reported elsewhere.

The most radical changes are reflected in the flint-working trade. Techniques seem to decline, and the materials used are inferior. The absence of the large chipped celt with a polished edge which is found in earlier Yucatán collections may point to a significant change in cultivation procedure. A common small celt form, on the other hand, appears as a new feature. Small arrowheads probably mark the introduction of the bow in warfare or hunting, and the rarity of larger stemmed points may mean a decline in the use of the spear thrower.

Obsidian flake blades were manufactured in great numbers, but there are few chipped implements. The fact that green obsidian, common in late periods in Mexico, is even more rare here than in early times in the Guatemala highlands suggests that, contrary to expectation and in spite of historical evidence of Mexican settlements at Xicalango, Mexican traders were not conspicuously successful in the Maya capital.

The collection of jades and other fine stone ornaments from Mayapán is disappointingly meager; this scarcity is due mainly, no doubt, to the fact that so many caches and tombs had been looted, but even from our small collections it is clear that few such objects were manufactured locally and that the best pieces were antiques when they were acquired.

Shell, bone, tooth, antler, and other organic materials exhibit ancient traditional techniques, which our shell collection illustrates somewhat better than other groups, containing, as it does, a large number of rejected pieces that often show technical process more clearly than does the finished product.

Proskouriakoff spent two months in Mérida this season classifying and studying the collections. Over 250 photographs were made by Sr. Raul Acuña, of Mérida, to serve as illustrations for the report now in preparation, which is designed to make this material available for comparison with collections from other cultures.

40.41.

ROBERT E. SMITH

Ceramic Studies in Yucatán

YB 56:410–412, 1957

During the past winter and spring, work was continued on the extensive collection of pottery from Mayapán. A year ago the study of the surface material was largely completed, including a separation and analysis of the pottery from what we are calling the Late Mayapán Ceramic Phase. Besides the late phase, an early and a middle phase of the Mayapán Ceramic Period (ca. 1200–1450 AD) appear to exist, and it was in their study that most of the time was spent.

It is interesting to review how the phases were determined in view of the rather inferior stratigraphic conditions at Mayapán: the scarcity of refuse dumps, none of which represents more than a single phase; the dearth of deep deposits; and the lack of marked architectural change. In order to determine the ceramic changes and therefore the possible ceramic phases, the material was separated into three groups according to level: the uppermost or surface the middle, and the lowest.

The uppermost level included material found in the humus or surface soil, on floors of rooms, or in fallen debris. Naturally, the pottery in the fallen debris is not necessarily contemporary with that found on the floors of rooms, but since these two groups are often hard to separate, and since no ceramic differences were noted, it was decided to lump them together as surface lots. Included in the surface lots is found a small percentage of earlier types, some of which came from fill (taken from early refuse deposits) mixed with fallen debris, some being early types still used, although in small quantities.

In separating the pottery of the lowest levels from the rest it was apparent that not all the lowest-level lots were typologically early; some might even belong with latest levels as far as the material was concerned. Therefore, in determining what was a truly early lowest level, we had to review the pottery to make certain that no late ceramic traits were present.

The middle lots include all those not considered surface or lowest and early. In this middle collection of potsherds we find Early as well as Late Mayapán Period traits. The early traits are found in smaller percentages, since they were gradually being discarded to make way for the late traits which were just coming in and which in the surface levels become predominant. The middle phase is essentially transitional.

The Mayapán Ceramic Period, believed to be approximately 250 years long, is represented through-

out by two principal wares: Mayapán Red and Mayapán Unslipped Porous Gray or Cinnamon. The red has minor shape changes from early to late and a few forms identified specifically with either the early or late phases. There may be typical middle-phase forms so far not identified. The story in the unslipped group is similar to that of the slipped red. Minor wares also play their part. Black on Cream Ware is well represented in the early, diminishes considerably in the middle, and disappears in the late phase. Cream Ware follows much the same pattern. Red on Buff and Red and Black on Buff, which may be considered subtypes of Mayapán Red, appear first in the middle but are most prolific in the late phase. There are other minor wares, of which some may be local but most are probably from trade. In the last category the most important is V Fine Orange, first noted in the middle but most abundant in the late phase.

In all levels, occasionally even in the surface lots, pre-Mayapán Period pottery occurs, including Puuc, Toltec-Chichén, and Petén-like Classic types. The appearance of these early types, mixed with material found in Mayapán Period levels, strongly suggests that they were taken from early deposits and refuse dumps and used for fill.

Another task completed this past season was the recording and analysis of the pottery from nine of the 19 cuts dug at Chichén Itzá in 1954 by E. M. Shook and R. E. Smith. The three objectives advanced in the report [Chapter 40.27 this volume] on that work were: to check the range of the site's occupation; to seek for refuse deposits, especially of long duration or in association with well known Maya and Toltec styles of architecture; to discover and record the full range and context of ceramics pertaining to the epoch of Toltec influence in Chichén Itzá.

The range of the site's occupation is marked by a small collection of formative sherds from one cut, whereas in all other cuts either Puuc or Toltec-Chichén types were present, although rarely in stratigraphic sequence. As for post-Toltec-Chichén pottery the situation remains the same as described in the above-cited report.

The second objective, a search for refuse deposits, was only partly successful. Only one deposit of long duration was encountered. Located behind the Temple of the Three Lintels, it disclosed nothing later than Puuc types below the floor and mostly Toltec-Chichén pottery above. The association of ceramic deposits with either Maya or Toltec styles of architecture is still inconclusive, primarily because no strictly architectural cuts were attempted.

The third objective, involving the range and context of the Toltec-Chichén Ceramic Period, has been successfully attained. There is nothing important to

add to the summary of that period given in [Chapter 40.27 this volume], although a very considerable amount of such material was encountered in the nine cuts examined this season.

40.42.

J. ERIC S. THOMPSON

Studies in Maya Religion and Hieroglyphs

YB 56:412, 1957

Thompson spent three weeks of March in Mérida, examining the effigy incense burners, recovered from Mayapán during the excavations. A few are complete, but most are fragmentary. The purpose of the study was to gather information on the religious cults of Mayapán and their bearing on late Maya history.

The incense burners are large pottery vessels, often as much as 60 cm high; to the front is attached the upright figure of a god. Parts of the figures, such as feet, arms, and faces were made in molds, details and differentiating characteristics being added in appliqué, and the parts joined with clay in a sort of primitive assembly line technique. From ethnological sources it is known that effigy incense burners portray specific members of the Maya pantheon.

After fragments too small to be identified as specific deities, and those that lacked specific characters, had been discarded, a total of 65 faces suitable for study remained. Their examination led to the identification of three Mexican deities in addition to Xipe, god of human sacrifice and of agriculture, recognized by Thompson in 1954. The first is Tlazolteotl, a mother goddess, whose original home may have been Veracruz, but whose cult was widespread among the peoples of the Mexican plateau. Tlazolteotl so closely parallels the Maya goddess Ixchel-Acna in functions that the fact that her cult was able to flourish in Mayapán is of considerable interest. It may suggest a deliberate effort to keep alive practices that separated the rulers of Mayapán, with their claims to Mexican ancestry, from the rank and file of the subjected peoples.

Another Mexican deity represented on a Mayapán censer is Tlauizcalpantecutli, "Lord of the Dawn," an aspect of the Venus god of the planet Venus. Finally, there is a god of merchants with a straight "Pinocchio" nose, who probably originated southern Mexico. None

of these Mexican gods is common, and the impression persists that they may have been worshipped by the relatively small group that comprised the ruling class at Mayapán.

On the other hand, Chac, the Maya rain god, who is depicted with great frequency in the Maya codices and at other Maya sites, appears somewhat infrequently on the effigy incense burners; the relative scarcity of this favorite deity of the Maya peasant in urban Mayapán, which was more interested in the political domination of the country than in farming, may be significant.

Thompson also visited the museums of Campeche and Villahermosa in search of comparative material.

In continuing work on his catalogue of Maya hieroglyphs, Thompson has carried out research on hi-

eroglyphs for disease in general and for particular diseases. He has identified parallel passages in two of Maya codices as divinatory almanacs for various diseases with a glyph for each complaint written in each compartment. Thompson made a popular presentation of his findings at the annual meeting of the Society for American Archaeology in Madison this past May in an endeavor to acquaint colleagues in the general field of anthropology with the nature of the problems of Maya hieroglyphic decipherment and how they are being attacked here.

Thompson also carried out research on the use of cacao in the religious and economic life of ancient Middle America and on fluctuations in its value as a currency in the colonial period. Results have appeared in a paper published by this Department.

41.0. UXMAL

The site of Uxmal, located in the Puuc hills of the Yucatán peninsula, has attracted many visitors since the time of the Mexican Independence, including Jean Frederic Waldeck in 1838, and John Lloyd Stephens and Frederick Catherwood in early 1840s. Désiré Charnay took a series of photographs of the site in the 1860, and three years later Empress Carlota of Mexico visited Uxmal. Sylvanus G. Morley made a map of the site in 1909 which included some previously overlooked buildings. The Mexican government consolidated some of the structures in 1927, and in 1930 Frans Blom made plaster casts of the façade of the Nunnery Quadrangle. These were later displayed at the 1933 World's Fair in Chicago. Further repair and consolidation was undertaken by José Erosa Peniche for the Mexican government in 1936. The Maya chronicles say that Uxmal was founded about 500 AD by Hun Uitzil Chac Tutul Xiu. For generations Uxmal was ruled over by the Xiu lineage. It was for a while in alliance with Chichén Itzá, and after about 1200 AD no new major construction was made at the site, possibly related to the fall of Chichén Itzá and the shift of power in Yucatán to Mayapán. The Xiu moved their capital to Maní,

and the population of Uxmal declined. After the Spanish conquest, during which the Xiu allied themselves with the Spaniards, colonial documents suggest that Uxmal was still an inhabited place of some importance into the 1550s. However, Uxmal was soon after largely abandoned. While much work has been done at Uxmal to consolidate and restore buildings, little serious excavation and research has been done. Most of the architecture visible today was built during the Late Classic period. Some of the more noteworthy buildings include the Governor's Palace, Pyramid of the Magician (Adivino), Nunnery Quadrangle, and the ballcourt. A number of others temple-pyramids, quadrangles, and other monuments, some of significant size, and in varying states of preservation, are also at Uxmal. A further suggestion of possible war or battle is found in the remains of a wall which encircled most of the central ceremonial center. A large raised stone causeway links Uxmal with the site of Kabah, some 18 km to the south.

41.1.

SYLVANUS G. MORLEY

Yucatán: Uxmal

YB 41:250–253, 1942

Dr. Morley returned to Yucatán by way of Mexico City in September 1941. While in Mexico City he delivered a lecture at the University Club, for the benefit of British war relief, on the archaeological investigations of the Institution during the past 25 years, and repeated the lecture in Spanish before the Sociedad Científica de Antonio Alzate.

During Dr. Morley's field work at Uxmal in the early part of 1941, a preliminary examination of the Great South Pyramid, a high, tree-covered mound southwest of the House of the Governor, revealed a section of a collapsed corbelled vault on the north or front side. This confirmed an impression, formed many years ago, that near the summit of this pyramid there had originally been ranges of rooms on each of the four sides. Dr. Morley devoted three weeks to excavations on all four sides of the pyramid, near the top, in order to establish the nature of the construction that had stood there.

The Great South Pyramid, the highest and largest at Uxmal, measures 96 m north and south by 80 m east and west, and is 27.5 m high from the north base to the summit. It is built on a slope which rises from north to south, so that its base at the south is 4 m higher than at the front. Two definite architectural periods were noted, and it is quite possible that the pyramid may contain still older constructions. The earliest building now visible consisted of a single range of at least four rooms, with long axes running east and west and doorways in their north walls. These were later incorporated into the northwest corner of the pyramid, their exterior back walls being covered by its masonry fill.

The pyramid proper was of 11 terraces, 10 at the back because of the southward rise of the terrain. The terraces, 1.4 m in vertical height, have battered faces. They are built of very roughly dressed stone like that of the substructure of the House of the Dwarf, and were finished with a heavy coat of plaster. There were no recessed panels or other decoration on the faces of these terraces. A centrally placed stairway on the north side, 23.5 m wide, projecting from the base of the pyramid and having about 70 steps, gave access to the uppermost terrace, which was also reached from the back by a somewhat narrower stairway, asymmetrically placed and in two offset flights.

On the highest terrace is a platform, 1.3 m high, all four faces of which are decorated with an elaborate sculptured mosaic, the principal elements being the

lattice pattern and the familiar Maya grecque. The platform is ascended by relatively narrow stairways of five steps each, at the north and south. On the platform, and built around and against a solid central core on the top of the pyramid, are four ranges of rooms; that on the front or north side seems originally to have consisted of five nonconnecting vaulted chambers entered by doorways in their north walls. The east, south, and west ranges, however, were almost entirely solid, there being only a single vaulted room at the middle of each; the long ends of all three, so far as could be determined, were of solid masonry. These four ranges of rooms are 6 m high.

At some later time, a second outer tier of three vaulted rooms had been built in front of the three middle rooms of the north range. When these were added, the floor level of the old middle room was raised 1 m above the floor level of the new chamber in front of it. The 1 m from the floor of the outer middle room to the sill of the doorway of the inner room was sculptured with a magnificent Maya mask 3.3 m wide and 1 m high, which is in a perfect state of preservation. Indeed, it seems probable that the level of the inner middle room was raised expressly to provide a surface for the presentation of this panel very closely resembles the mask panel in an identical position in the middle outer room of the palace at Kabah.

The solid central core of the pyramid, surrounded by these four ranges, rises another 1.7 m above the level of their respective roofs. There seems never to have been any construction on its summit, or any stairway ascending to it from the level of the sculptured terrace which supported the rooms.

As a second major constructional undertaking, the pyramid was covered from bottom to top with a layer of rubble 1.5 m thick, much of it composed of dry-laid, large, irregularly shaped pieces of limestone. The surface of this rough covering, completely enclosing not only the stucco faced, terraced pyramid and sculptured upper terrace but, also the elaborately ornamented façades of the four ranges of rooms, would also seem to have been terraced, though these later terraces are much broken down.

A possible reason for the encasement of the pyramid and its superstructure may have been that the sculptured façades of the four ranges of chambers had begun, soon after they were built, to fail, to crack, and bulge outward so seriously that it became necessary, in order to keep the whole upper part of the pyramid from crashing down, to give it the support of added masonry, especially at the top where it could sustain the falling façades and prevent them from pushing outward. Incidentally to these operations, the ranges of rooms were filled solidly with dry-laid rough rubble, and the entire construction was converted into a great

new pyramid, the main stairways on its north and south sides still being retained. It is probable that eventually this larger pyramid would have served as substructure for some sort of building had not final collapse of the Maya in the thirteenth and fourteenth centuries halted this grandiose project before its crowning structure could be erected.

Owing to the burial of the elaborately sculptured façades of the building near the top before they had been exposed too much weathering, the façades were in practically perfect preservation. The north façade bears an intricate mosaic in both the upper and lower zones, in which panels decorated with geometric designs, grecques, and so forth, appear. On the east, south, and west the upper zones only are decorated, the lower zones being of plain dressed stone.

Such is the beauty of the mosaic, the grace of the proportions, the size and commanding height of this pyramid, that it must in its day, have been the most arresting building in the city.

As nothing like complete excavation could be attempted in the time available only such trenches were

dug, on the four sides and at the four corners near the top, as would permit the making of ground plans and elevations. The style of architecture indicates that the building was erected at the very height of the Puuc period, perhaps during the twelfth or thirteenth century. Some associated ceramic material was found, and two human skeletons, the bones and crania gone to powder.

In addition to the work on the Great South Pyramid, the Northwest Group was entirely bushed, and a map and north-south cross section were made. This group has become of the earliest masonry found at Uxmal; the flat building stones are only very roughly dressed, and in some cases extend clear through the walls; both exterior and interior surfaces undoubtedly were plastered.

Dr. Morley left Yucatán April 8, 1942. He delivered the Benjamin Franklin Medal Lecture before the American Philosophical Society at Philadelphia April 23, and is spending the summer at Santa Fe, New Mexico, where he has had summer offices at the Laboratory of Anthropology for many years.

42.0. YAXUNÁ

Yaxuná is a relatively small site located approximately 20 km south of Chichén Itzá. The structures of Yaxuná were some of the largest constructions in the northern Maya lowlands erected during the Middle Preclassic and Classic periods, and the longest known causeway (sacbé) extends from Yaxuná to Cobá, 100 km to the east. A boundary settlement of Cobá, Yaxuná eventually fell victim to conquest by Chichén Itzá. The site was surveyed by John P. O'Neill and Gustav Strömsvik in the 1930s. In the late 1940s and early 1950s, George Brainerd surveyed the site and reported pottery from the east and west coasts of Yucatán, specifically from Cobá and from the Puuc region.

42.1.

JOHN P. O'NEILL

Survey of Yaxuná

YB 32:88–89, 1933

The ruins of Yaxuná, located a short distance to the south of Chichén Itzá, are archaeologically important because their architecture differs strongly from that of Chichén, because they are allied ceramically to the cities of the Puuc and Cobá, and because they form the apparent terminus of the great ancient highway running westward from Cobá. In preparation for possible future excavations, Mr. O'Neill and Mr. Strömsvik devoted a week in early February to mapping the site.

Yaxuná is reached from Chichén Itzá in seven hours on horseback by a trail which runs from Pisté to the ruined hacienda of Xcolup and thence through the village of Yaxuná; or in six hours via Old Chichén and Yulá. The present Maya village of Yaxuná lies about 1 km west of the ruins.

The survey began by a preliminary examination from the top of a high, centrally located pyramid. It and all other structures rise from a flat plain covered with a low, sparse growth of bush. This permitted the establishment by triangulation of reference points

upon all important platforms or pyramids, from which traverse lines were run wherever necessary. Measurements were made almost entirely by stadia readings, the tape being used only in rare instances where walls were discernible, or for determining short distances upon mounds.

The site is roughly diamond shaped, the short axis measuring about 0.5 km, and the long axis (north by northeast) a little less than 1 km. This layout includes a group to the south not before reported. A cenote near the ruins was found to be 300 m, N 53 W, from the northwest corner of the platform which supports the northernmost pyramids and the only standing struc-

ture at the site. A large artificial mound is said by the natives to stand 1 km north of this cenote.

On a clear day, when the sun is near or past the meridian, the Castillo at Chichén can be seen from the high central pyramid of Yaxuná. Under especially favorable conditions some of the other structures at Chichén are visible by the aid of the theodolite. Observations for bearing and distance were therefore made, which show Yaxuná to be 17.8 km, S 32 degrees 00'W (true) from the Castillo. Referring to the recorded position of the Castillo at Chichén, the latitude of the ruins of Yaxuná is 8.3', or 20 degrees 32.6'N; and the longitude, +5'30", or 88 degrees 39'40"W.

APPENDIX I

CARNEGIE INSTITUTION OF WASHINGTON ARCHIVES

The Carnegie Institution of Washington is located at 1530 P Street, NW, Washington, DC, 20005. A guide to the administrative records of the Carnegie Institution of Washington is available online at www.carnegieinstitution.org/archives.pdf and contains approximately 200 titles pertaining to the CIW Maya Program. These documents include correspondence, financial documents, articles, biographies, maps, publications, reports, news clippings, and miscellaneous items.

Director's correspondence includes S. G. Morley (1903–1928), A. V. Kidder (1934–1949), and H.E.D. Pollock (1950–1965).

Correspondence between the CIW, project members, and others, includes J. M. Dimick (1940–1941), M. Gamio (1923–1931), A. V. Kidder (1925–1932), S. G. Morley (1912–1918, 1929–1951), E. H. Morris (1925–1956), H.E.D. Pollock (1936–1979), T. Proskouriakoff (1959–1974), O. G. Ricketson (1934–1935), A. O. Shepard (1936–1973), S. Tax (1934–1949), E. H. Thompson (1911–1934), and J.E.S. Thompson (1947–1958).

Research correspondence includes Allotments (1919–1930); Bonampak Expedition (1946–1949); Buildings, quarters, and grounds (1905–1953); Chichén hacienda (1924–

1944); Closing of the Department of Archaeology (1956–1969); Copan Project (1934–1940); Equipment (1917–1963, 1967); Fieldwork (1924–1929, 1932, 1933); Finances (1919–1931); Funds (1921–1926, 1930); Guatemala contract renewal (1930–1948); Historical research (1936–1958); Leases (1923–1961); Maya glyph catalog (1961); Mesoamerican archaeological research (1922–1942); Mexican contracts renewal (1931–1955); Publications (1903–1936); and Quiriguá stela removal (1931).

Financial records include information on allotments (1904–1944), budgets (1903–1933), finance (1924–1959), finance budget (1969–1970), financial statements (1954–1958), and receipt of funds (1922–1927).

Individual finance and expense records are available for T. Proskouriakoff (1959–1973), R. Redfield (1945), R. L. Roys (1949–1952), K. Ruppert (1946–1955), W. T. Sanders (1953–1957), F. V. Scholes (1946), A. O. Shepard (1958–1969), E. M. Shook (1946–1955), A. L. Smith (1945–1959), P. Smith (1954), R. E. Smith (1941–1951, 1953–1957), G. Stromsvik (1946–1955), S. Tax (1945–1948), C. Tejada (1947), C. Temple (1955), D. Thompson (1955), J.E.S. Thompson (1951–1959), R. Thompson (1950–1951), A. Villa Rojas (1945–1947), H. Williams (1949), and H. D. Winters (1954).

APPENDIX 2

ARCHAEOLOGICAL ARCHIVES OF THE CARNEGIE INSTITUTION OF WASHINGTON, PEABODY MUSEUM OF ARCHAEOLOGY AND ETHNOLOGY, HARVARD UNIVERSITY

The archaeological papers of the Carnegie Institution of Washington Maya program were deposited in 1958 at the Peabody Museum of Archaeology and Ethnology, Harvard University, Cambridge, Massachusetts, 02138. The records of the Archaeology Division of the Carnegie Institution of Washington, 1919–1958 (inclusive), take up approximately 75 linear feet of space and include filed notebooks and diaries; maps, plans and section drawings; specimen cards; architectural and pencil drawings; watercolor paintings; photographs; correspondence; research reports; and manuscripts. Various materials, accessioned and unaccessioned, have been added to the collection, especially by Ian Graham, Gordon R. Willey, and other former Carnegie investigators (Swerdlow and Demb 2000).

PHOTOGRAPHIC ARCHIVES

The most significant related collection is the Carnegie Institution of Washington Photographic Collection, consisting of 35,000 negatives and maintained in the Peabody Museum Photographic Archives. Approximately 2,500 images, especially of Chichén Itzá, Copán, Mayapán, Piedras Negras, and Uaxactún, are digitized at <http://www.peabody.harvard.edu/col/default.cfm>.

OTHER RELATED COLLECTIONS

Other related collections at the Peabody Museum include the papers of Charles P. Bowditch, Carl E. Guthe, Alfred V. Kidder, Sylvanus G. Morley, Tatiana Proskouriakoff, Oliver G. Ricketson, Karl Ruppert, Edward H. Thompson, J. Eric S. Thompson, and Alfred M. Tozzer, as well as the Chichén Itzá Expedition Records and the Central American Expedition Records.

Other archival collections at the American Philosophical Society in Philadelphia (Alfred V. Kidder and Sylvanus G. Morley); British Museum Department of Ethnography Library (J.E.S. Thompson); Harvard University Archives (Alfred V. Kidder,

Clyde K.M. Kluckhohn, and Tatiana Proskouriakoff); National Anthropological Archives (T. Dale Stewart, Sol Tax, and Walter W. Taylor); National Geographic Society (974 photographs from Yucatán in the 1950s); National Museum of Health and Medicine (Morris Steggerda); University of California Bancroft Library (Lila O'Neale); University of Chicago Library (Robert Redfield and Sol Tax); University of Colorado, Boulder (Earl H. Morris and Anna O. Shepard); University of Michigan Harlan Hatcher Graduate Library (Carl E. Guthe); and University of Washington Libraries (Ralph L. Roys).

ARCHAEOLOGY

Adams, R. M., field notebooks, 1953 (3 v).

Album of unpublished photographs of monuments and rubbings of inscriptions at Calakmul, La Muñeca, Rio Bec II, Rio Bec V, Alta Mira, Naachtún, Oxpemul, Balakbal, Uxul, Pasión de Cristo, and Pechal, 1943.

Amsden, M., field notebook, Uaxactún, 1928.

Andrews, E. W., field notebooks: Campeche, 1940 (2); Yucatan, 1940 (2); Mayapan, 1942 (3).

Berlin, H., field notebooks, Tabasco Survey, 1952–1955 (5 vols.); supplementary illustrations for *Current Reports*, 7, n.d.

Boggs, S. H., field notebooks: Tazumal, 1944; El Salvador, 1947, 1950; unidentified, 1947; Campana San Andres, field notes and section drawings, n.d.; drawings for Tazumal report, n.d.; San Andres drawings, n.d.

APPENDIX 3

ETHNOGRAPHIC FIELD NOTES, CARNEGIE INSTITUTION OF WASHINGTON, UNIVERSITY OF CHICAGO

Notes of ethnographic field research conducted under the auspices of the Carnegie Institution of Washington by Robert Redfield in Yucatán and Sol Tax in the Guatemala highlands, and linguistic studies by Manuel J. Andrade, Norman A. McQuown, and other researchers from the University of Chicago, are reproduced in the *Manuscripts on Middle American Cultural Anthropology* (series 1–7, nos. 1–51), *Manuscripts on American Indian Cultural Anthropology* (series 8–14, nos. 52–92), and *Microfilm Collection of Manuscripts on Cultural Anthropology* (MCMCA; series 15, nos. 95–). The collection originally covered only Mesoamerican cultures and American Indians but was later expanded to include cultural anthropology in general. Most of the collection consists of linguistic materials: grammar notes, vocabularies, dictionaries, phonology, linguistic atlases, texts, translations, field data, and also materials on ethnography. Documents pertaining to field notes collected under the auspices of the Carnegie Institution of Washington include the following items:

Andrade, Manuel J. 1946a. Materials on the Huastec language. MCMCA, 9. Full posthumous field notes done in 1930 and 1933 among the Potosí and Vera Cruz Huastec Indians of Mexico.

Andrade, Manuel J. 1946b. Materials on the Kekchí and Pokomam languages. MCMCA, 12. 474 leaves. Posthumous field notes of work done for the Carnegie Institution of Washington in 1936 and 1938 in central and northern Guatemala.

Andrade, Manuel J. 1946c. Materials on the Mam, Jacalteco, Aguacateco, Chuj, Bachahom, Palencano, and Lacandon languages. MCMCA, 10. 1,152 leaves. Full posthumous field notes of work done for the Carnegie Institution of Washington in 1931, 1935, and 1937 among Maya groups in Chiapas and western Guatemala, including Mam texts transcribed by Rev. Horace D. Peck, Mrs. Dorothy Peck, and Rev. Edward F. Sywulka.

Andrade, Manuel J. 1946d. Materials on the Quiché, Cakchiquel, and Tzutuhil languages. MCMCA, 11. 942 leaves. Full posthumous field notes of work done for the Carnegie Institution of Washington in 1935–1936 in central Guatemala; includes Cakchiquel texts written and translated by Juan de Dios Rosales and an English-language summary of the texts by Gertrude Tax.

- Andrade, Manuel J. 1956. A grammar of modern Yucatec. MCMCA, 41. 462 leaves. Brought almost to completion before the author's death and subsequently arranged by S.L.K. Bradshaw; based on a large accumulation of Yucatec materials in the files of the Macro-Mayan Project of the Department of Anthropology at the University of Chicago.
- Andrade, Manuel J. 1971. Yucatec Maya texts. MCMCA, 108. Preliminary transcription and translation; recorded by Manuel J. Andrade; transcribed and translated by Refugio Vermont-Salas; transcriptional system, Norman A. McQuown.
- Andrade, Manuel J. 1975. Huastec text word: Concordance, texts recorded on aluminum discs by Manuel J. Andrade; transcribed and translated by Norman A. McQuown; concordanced on the basis of a revised and updated version of programs by A. James Trubulsee. MCMCA, 166. 1558 p.
- Andrade, Manuel J. 1976a. Mam texts, disc-recorded by Manuel J. Andrade, 1935; transcribed and translated by Dorothy Peck, 1950–1951; key-punched by Lois Bisek, 1969–1970. MCMCA, 106.
- Andrade, Manuel J. 1976b. Quekchi texts, recorded or taken down from dictation by Manuel J. Andrade in 1939; with interlinear Spanish translation. MCMCA, 170.
- Andrade, Manuel J. 1977a. Mam miscellany: vocabulary, verb conjugation. MCMCA, 302. 28 leaves.
- Andrade, Manuel J. 1977b. Mopán notes, with Yucatec, Itzá, and Quekche, gathered in Bacalar, Corozal, San Luis, San Antonio, Belize in 1931 by Manuel J. Andrade. MCMCA, 246.
- Andrade, Manuel J. 1977c. Yucatec Maya stories, taken down from dictation with various informants; transcribed and translated into Spanish (interlinear) and English, 1931. MCMCA, 262.
- Andrade, Manuel J., and Remigio Cochojil-González. 1971. Quiché (Maya) texts. MCMCA, 111. 784 leaves. Disk-recorded in 1935 by Manuel J. Andrade and transcribed and translated into Spanish by Remigio Cochojil-González in 1964–1971; transcriptional system by Norman A. McQuown.
- Andrade, Manuel J., and Alfred V. Kidder. 1976. Notes on “Choltí” and “Chortí”: on an anonymous author's “Choltí,” on Charles Wisdom's Chortí, on Ernest Noyes Chortí, 1976. MCMCA, 158.
- Andrade, Manuel J., and Norman A. McQuown. 1971. Textos huastecos, 1970. MCMCA, 103. 250 leaves.
- Baer, Philip, and Mary Baer. 1950. Materials of Lacandon culture of the (Pelhá) region. MCMCA, 34. 334 leaves. Field notes from a study in the Lake Nahal area, in the material culture, social structure, kinship terminology, division of labor, economics, and life cycle, psychology and belief system, and religious culture.
- Blair, Robert W., Refugio Vermon Salas, and Norman A. McQuown. 1978. Spoken Yucatec Maya: Book 1 (Lessons 1–12), 1978. MCMCA, 110. 656 leaves.
- Blair, Robert W., Refugio Vermon Salas, and Norman A. McQuown. 1993. Spoken Yucatec Maya: Book 1, Lessons 1–6. MCMCA, 411.
- Cámara Barbachano, Fernando. 1945a. Monografía de los tzotziles de San Miguel Mitontik, Chiapas, Mexico. MCMCA, 6. 90 leaves. Original field notes of a study made in 1944 in Chiapas, Mexico, as part of the joint expedition of the Instituto Nacional de Antropología e Historia de México, the State of Chiapas, and the University of Chicago, with a grant supplied by the Viking Fund, with the cooperation of the Carnegie Institution of Washington.
- Cámara Barbachano, Fernando. 1945b. Monografía sobre los tzeltales de Tenejapa, Chiapas, Mexico, 1945. MCMCA, 5, xxxiv, 522 leaves. Original field notes of a study made in 1943–1944 in Chiapas, Mexico, as part of the joint expedition of the Instituto Nacional de Antropología e Historia de México, the State of Chiapas, and the University of Chicago, with a grant supplied by the Viking Fund, with the cooperation of the Carnegie Institution of Washington.
- Cámara Barbachano, Fernando. 1947. Notas sobre Zinacantán, Chiapas, por miembros de la expedición a Zinacantán, 1942–1943 bajo la dirección de Sol Tax; primera parte, capítulos sobre la organización religiosa-política. MCMCA, 20. 304 leaves. Original field notes of a joint expedition of the Escuela Nacional de Antropología e Historia de México, the State of Chiapas, and the Carnegie Institution of Washington Middle American Research Program.
- Dios Rosales, Juan de. 1949a. Notes on Aguacatán. MCMCA, 24. 99 leaves. Diary and notes of a three-month stay in Aguacatán, Huehuetenango, Guatemala, by the author and Agustin Pop, in connection with the Carnegie Institution of Washington survey of food habits in Guatemala, under the direction of Sol Tax. In addition to the miscellaneous notes contained in the diary, there is a systematic description of various aspects of the culture.
- Dios Rosales, Juan de. 1949b. Notes on San Pedro La Laguna. MCMCA, 25. 944 leaves. Original field notes collected during a thirteen-month study (1938–1939) of San Pedro La Laguna of approximately 2,000 Tzutujil Maya, under the direction of Sol Tax as part of the Carnegie Institution of Washington Middle American Research Program.
- Dios Rosales, Juan de. 1950. Notes on Santiago Chimaltenango. MCMCA, 30. 40 leaves. Diary and notes of a two-month stay during winter 1941, in connection with the Carnegie Institution of Washington Survey of food habits in Guatemala under the direction of Sol Tax.

- Dios Rosales, Juan de. 1976. Cakchiquel texts, vocabularies, and miscellaneous notes, noted down in the 1930s and 1940s. MCMCA, 123. 240 leaves.
- Dios Rosales, Juan de. 1987. Cakchiquel texts, 1987. MCMCA, 124. 502 leaves.
- Fisher, William M., and Norman A. McQuown. 1990. Toward the reconstruction of proto-Yucatec; William M. Fisher and Norman A. McQuown, Yucatec Maya root list; William M. Fisher, On tonal features in the Yucatecan dialects. MCMCA, 263–265.
- Goubaud Carrera, Antonio. 1949a. Notes on San Juan Chamelco, Alta Verapaz. MCMCA, 23. 163 leaves. Diary of a three-month visit to San Juan Chamelco, a Kekchí community of Alta Verapaz, Guatemala, in connection with the Carnegie Institution of Washington survey of food habits in Guatemala, under the direction of Sol Tax.
- Goubaud Carrera, Antonio. 1949b. Notes on the Indians of Eastern Guatemala. MCMCA, 22. 90 leaves. Diary of a two-month stay in Jocotán (Chortí) and a two-month stay in San Luis Jilotepeque (Pokomam), Guatemala, in connection with the Carnegie Institution of Washington survey of food habits in Guatemala, under the direction of Sol Tax.
- Goubaud Carrera, Antonio. 1949c. Notes on the Indians of the Finca Nueva Granada. MCMCA, 21. 35 leaves. Diary of a one-month visit to a coffee plantation in connection with the Carnegie Institution of Washington survey of food habits in Guatemala, under the direction of Sol Tax.
- Goubaud Carrera, Antonio, Juan de Dios Rosales, and Sol Tax. 1944. Reconnaissance of northern Guatemala. MCMCA, 17. 181 leaves. Original field notes of a trip across northern Guatemala in 1944; made as part of a survey of food consumption habits in Guatemala, as part of the Carnegie Institution of Washington Middle American Research Program.
- Guiteras Holmes, Calixta. 1945. Informé de Cancuc, 1945. MCMCA, 8. 30,388 leaves. Original field notes of a study made in 1944 in Chiapas, Mexico, as part of the joint expedition of the Instituto Nacional de Antropología e Historia, the State of Chiapas, and the University of Chicago, with a grant supplied by the Viking Fund, and with the cooperation of the Carnegie Institution of Washington.
- Guiteras Holmes, Calixta. 1946. Informé sobre San Pedro Chenalhó. MCMCA, 14. 25,378 leaves. Original field notes of a study made in 1944 in Chiapas, Mexico, as part of the joint expedition of the Instituto Nacional de Antropología e Historia, the State of Chiapas, and the University of Chicago, with a grant from the Viking Fund, and with the cooperation of the Carnegie Institution of Washington.
- Larsen, Ramón, and Norman A. McQuown. 1981–1983. Vocabulario huasteco del estado de San Luis Potosí, 1981–1983. MCMCA, 168–169. Compiled by Ramón Larsen during 1940–1954 and re-edited by Norman A. McQuown.
- Materials on the Mayan languages of Mexico: texts and dictionaries in Chol, Tojolabal and Tzotzil, by field workers of the Summer Institute of Linguistics, during the period 1939–1948. MCMCA, 26. Contains Chol texts recorded by Ruth Hitchner Yourison; Chol dictionary by Evelyn Woodward Aulie; Tojolabal texts and dictionary by Cecilia Douglas Mendenhall and Julia Supple; and Tzotzil texts and dictionary by Nadine Douglas Weathers.
- McQuown, Norman A. 1940. Gramática de la lengua totonaca (Coatepec, Sierra Norte de Puebla), 1987. Translation of the author's doctoral dissertation, Yale University. MCMCA, 101.
- McQuown, Norman A. 1957. El Tzeltal hablado; basado en Hablemos en Tzeltal por Carlo Antonio Castro G., Instituto Nacional Indigenas, San Cristobal Las Casas, Chiapas, México, 1955 reelaborado provisto de notas gramaticales, ejercicios, vocabularios, e índices léxicos tzeltal-español y español-tzeltal. MCMCA, 320. 311, 69, and 49 leaves (429 leaves total).
- McQuown, Norman A. 1962. Huehuetenango vocabularies. MCMCA, 58. 696 p. Vocabularies from twelve towns, including San Miguel Acatán, San Rafael la Independencia, Jacaltenango, Concepción, San Marcos, San Andrés, Todos Santos Cuchumatán, San Mateo Ixtatán, Santa Eulalia, San Mateo Ixtatán, San Sebastián Coatán, San Juan Ixcay, and San Pedro Solomá; collected on magnetic tape and transcribed by Brent Berlin, Nicholas A. Hopkins, and Norman A. McQuown.
- McQuown, Norman A. 1976a. Huastec morpheme list: Huastec-Español, assembled in 1946–1947 in the field, in Tancanhuitz, San Luis Potosí, Mexico; computer print-out of card images. MCMCA, 167. 739,153 p.
- McQuown, Norman A. 1976b. Quekchi vocabulary: recorded November 25–26, 1948. MCMCA, 171.
- McQuown, Norman A. 1976c. Textos kanjobales; grabados en discos de aluminio, por Manuel J. Andrade, con informantes Francisco Pedro de Santa Eulalia y Domingo Castañeda de Santa Cruz Barillas, Huehuetenango, Guatemala; transcritos por él y por Newberry Cox. MCMCA, 196.
- McQuown, Norman A. 1976d. Vocabulario chol recopilado el 15 de noviembre de 1949, con la ayuda de John Beekman, en Tuxtla Gutiérrez, Chiapas, México, con Mateo Vásquez, indígena chol de la Cueva, Chiapas. MCMCA, 156. 25 leaves.

Francisco Dominguez . . . ; mecanoscrito por Norman A. McQuown. MCMCA, 186.

APPENDIX 4

FRANCE V. SCHOLÉS COLLECTION, LATIN AMERICAN LIBRARY, TULANE UNIVERSITY

The France V. Scholes Collection, curated at the Latin American Library, Tulane University, consists of approximately 280,000 photoprints, microfilms, and typescripts of documents relating to the history of colonial Spanish America found in Spanish and Mexican archives, principally the Archivo General de Indias in Seville and the Archivo General de la Nación in Mexico City, and collected primarily under the auspices of the Carnegie Institution of Washington (<http://www.tulane.edu/~latinlib/scholescoll.html>).

The content of the documentation may be described, in general terms, under the following topical headings:

1. Documents that illustrate the character of Spanish colonial government and policy in the sixteenth and early seventeenth centuries with special reference to Mexico.
2. Documents that illustrate, in more specific detail, problems and policies of administration of the Indian population of Spanish America (with special emphasis on Mexico) in the sixteenth to the eighteenth centuries, and particularly with reference to the encomienda system, forced labor for wages, and chattel slavery.
3. Materials relating to the Spanish conquest of Mexico and Guatemala, including several thousand pages of photoprints of the *probanzas* of merits and services of prominent conquistadores (including the Alvarado brothers) and the residencia of Pedro de Alvarado as governor of Guatemala.
4. Documents that illustrate the life and times of Hernando Cortes from 1521 (the year of his final victory over the Aztec Confederacy) to his death in Spain in 1547. These materials deal principally with the history of events in the chaotic decade of the 1520s, and with the history of the estate (Marquesado del Valle) founded by Cortes. The documentation on Cortes and his times, 1521–1547, includes the residencias of Cortes, the First Audiencia of Mexico, and early *alcaldes mayores* of Oaxaca. Scholes considered his collection of Cortes material the most extensive collection of unpublished Cortes documentation in the world.

5. Selected documents relating to the history of the Cortes Estate subsequent to 1547, especially with reference to litigation concerning execution of various provisions of Cortes's last will and testament.
6. Selections from the correspondence of the viceroys and treasury officials of Mexico (sixteenth century), and miscellaneous documents on various topics of sixteenth-century Mexican history.
7. Extensive documentation relating to the history of Yucatán and the Maya area in the sixteenth and seventeenth centuries. The documentation has value not only for students of colonial Spanish American and Mexican history, but also for those specializing in other disciplines, such as anthropology, ethnohistory, and art history.

The corpus of material consists of the following items:

1. 180,000 units of enlargement photoprints from microfilm or, in a few cases, prints from photostat negatives. The size of these photoprints varies: some are 7½ x 10 inches; others are letter size (8½ x 11 inches); but the majority are legal size, that is, 11 x 14 inches or 11 x 16 inches. It should be noted that most of the photo-enlargement prints (and also films mentioned below) reproduce two pages of manuscript documentation.
2. 70,000 frames, or exposures, of 35 mm negative microfilm of documents.
3. 15,000 pages (letter size) of typescripts of documents.
4. The Archive File consisting of 12,000 to 14,000 cards (4 x 6 inches) that record data concerning content and organization of Spanish and Mexican archives with notations concerning documents reproduced, and also notations concerning documents examined, which may be useful for students of colonial Spanish American history.

Access to the documents may be obtained by consulting the index card of documents description that Scholes prepared. The documents follow the order of this card index. These cards identify the documents by their archive provenance, provide a brief description of the documents or their titles, and indicate the form of reproduction (i.e., photoprints, microfilm, typescripts, or in a few cases, handwritten cards) with the number of photographs, exposures, or pages. They are arranged alphabetically by archive and section, with the Spanish archives first, followed by the Mexican archives, then by other repositories. The arrangement of documents in the filing cabinets and of the microfilm in boxes is in the same order. The collection consists of reproductions of documents from the following archives and sections. The photoprints are found in the indicated filing cabinets.

ARCHIVES OF SPAIN

Archivo de Protocolos, Sevilla (APS); Archivo General de Indias, Sevilla (AGI): Contaduria, Contratacion, Escribania de Camara, Estado, Guadalajara, Guatemala, Indiferente General, Justicia, Mexico, Patronato; Archivo Historico Nacional, Madrid (AHN): Cartas de Indias, Inquisicion, Ordenes Militares; Biblioteca Nacional, Madrid (BN); Real Academia de la Historia, Madrid (RAH): Coleccion Muñoz, Coleccion Vargas Ponce.

ARCHIVES OF MEXICO

Archivo General de la Nacion (AGN): Alcaldes Mayores, Archivo Historico de Hacienda, Bienes Nacionales, Civil, Clero, Congregacion, Cruzada, Historia, Hospital de Jesus, Indiferente General, Indios, Inquisicion, Mercedes, Ordenanzas, Real Acuerdo, Real Hacienda, Reales Cédulas (Originales; Duplicados), Tierras, Vinculos; Archivo Parroquial de la Catedral de Merida, Yucatán: Libro de Bautismos y Matrimonios; Archivos Parroquiales de Campeche, Campeche: Libro de bautizos, matrimonios, etc.; Biblioteca Nacional, Mexico: Archivo Franciscano; Museo Nacional, Mexico: Matricula de Tributos.

MICROFILMS

The microfilms duplicate part of the material found in photoprint from, except for a few instances in which the microfilm is the only copy. This information is noted on the cards of the indexed document descriptions. The content of the twenty-eight boxes of microfilm include the following items:

Archivo General de Indias: Contaduria 806; Escribania de Camara 163A, 204A-7, 304B-5, 308B-30; Guatemala 151-153; Guatemala 343; Indiferente 81; Justicia 3-139, 141-205(4), 206(2)-234, 242-712(1-2), 1017(3)-1144(3); Mexico 91-995; Patronato 182, 237.

Archivo General de la Nacion: Archivo Histórico de Hacienda, Civil, Clero, Hospital de Jesús 235, 247-285(99), 288-293, 300-387(9), 394-432(2); Hospitales; Reales Cédulas Duplicados, Tierras 1520(2), (3082); Vinculos 4-276.

Biblioteca Nacional; RAH: MS A-57, MS 27-5E-131.

Real Academia de la Historia, Madrid: Vargas Ponce; El Escorial: Documents on the customs of the Chichimecas Indians and justification of war with them; 1542 list of the men who were conquistadors with Cortes, with and without encomiendas of Indians, sixteenth century (MS K-11-8, ff. 392-418; MS S-11-7, ff. 331-343; MS S-11-7, ff. 423-456).

SCHOLES ARCHIVE FILES

The Scholes Archive Files consist of some 12,000–14,000 handwritten cards. It provides a more comprehensive record of the contents of the Spanish and Mexican archives than that recorded in the index file of document descriptions and contains Scholes's comments concerning these archives and information on documents not included in the collection. The contents of the Archive Files are the following items:

Archivo General de Indias: Audiencia-Contaduría (Leg. 657, nos. 1–4, ramos 1–4; 659, 660, 911A-B, 913). Royal treasury and taxation records for New Spain, sixteenth and seventeenth centuries; Contratación (Leg. 1675A-B). Royal treasury accounts of New Spain, sixteenth century, Guatemala. Documents on the treatment, reducción of Indians, affairs in Guatemala and Honduras, sixteenth and seventeenth centuries, Indiferente. Registries of reales ordenes. Indian affairs, petitions, personal affairs in New Spain, sixteenth and seventeenth centuries, Justicia. Civil and criminal lawsuits in New Spain, regarding property, money, taxation, grievances, and especially encomiendas of Indians, many concern Hernando Cortes, the first Audiencia of New Spain, Nuño de Guzmán, and Pedro de Alvarado. Also the residencias of Cortes, Guzmán, Alvarado and others, early sixteenth century; Mexico (leg. 1–3201). Reales cédulas for New Spain. Letters and official documents of viceroys and oidores of New Spain; merits and services of conquistadors, tax records, petitions; papers of government officials of Yucatán and documents regarding Indian labor and affairs, sixteenth through eighteenth centuries Patronato (leg. 1–179, 180–294). Documents regarding founding of cathedral and churches in New Spain, first Bishop Zumarraga and treatment of Indians; documentation on Cortes, on discoveries, merits, and services of conquistadors, including those with Cortes, the Alvarado family in Guatemala, and Bernal Díaz del Castillo; information on Doña Marina and succession of Montezuma; documents on affairs in Hispaniola, Cuba, and road from Yucatán to Guatemala; records of taxes owed Crown in 1571, sixteenth century.

Archivo General de la Nación: Alcaldes Mayores, Hospital de Jesús; Reales Cédulas-Tierras; Biblioteca Nacional de México. Included are temporary cards in Scholes's handwriting. They parallel the material found in the card index. A few of the documents listed in the card index of document descriptions are noted as missing. These documents were either not received from Scholes in the original shipments or were sent back to him for further research and not returned. The index contains France V. Scholes's notations and correlations with the modern classification in the archive

and these correspond to many items in the LAL Scholes Collection, University of New Mexico Library; France V. Scholes Papers; Scholes's correspondence with distinguished Latin American historians and anthropologists, his personal notebooks, and copies of documents from the AGI and AGN, covering major figures and topics in the ethnohistory of early colonial Mexico (ca. 50 boxes).

RELATED COLLECTIONS

Tozzer Library, Peabody Museum of Archaeology and Ethnology, Harvard University, was the repository for a collection of manuscript facsimiles, transcripts, and extracts relating to the Spanish conquest of the lowland Maya of southern Mexico and Guatemala, and the development of early Hispano-Indian society in the colonial provinces of New Spain and Yucatán. These materials cover the period from 1520 to 1800, with the periods 1570 to 1579 and 1640 to 1720 represented most thoroughly. Most of these papers were assembled during the 1930s by France V. Scholes, Eleanor B. Adams, and Robert S. Chamberlain at the Archivo General de Indias in Seville, Biblioteca Nacional in Madrid, Archivo General de la Nación in Mexico City, and Archivo Notarial in Mérida. After the closing of the CIW Maya research program in 1958, these documents were held by Scholes until the middle 1960s when they were donated to Tozzer Library. Duplicate copies of some reproductions were deposited in the Latin American Collection (Miscellaneous) Section, Division of Manuscripts, of the Library of Congress in Washington, D.C.

The scope and contents of the various groups of documents indicate the importance of the collection for basic ethnohistorical research. General coverage summarized by the following themes:

1. Selected letters and petitions of private individuals, secular and ecclesiastical, to the viceroyalty of New Spain.
2. Miscellaneous documents regarding Indian administration, especially problems of personal service, perpetuity of encomiendas, and levy of tithes, in New Spain.
3. Letters from treasury officials of New Spain.
4. Memorials, reports, and litigation relating to controversies between royal officials and local Spanish ruling minorities in the sixteenth and seventeenth centuries.
5. Documents dealing with military and missionary activities in the Petén and Verapaz regions of Guatemala in the late seventeenth century.
6. Letters and reports of provincial governors of the province of Yucatán between 1644 and 1750.
7. Maya linguistic material from various residencias of Yucatán.

8. Matricula of encomienda Indians in Yucatán from 1688.
9. Trial records detailing encomienda administration in early Colonial-period Yucatán.
10. Proceedings relating to Landa's auto-defé against idolatry in sixteenth-century Yucatán.
11. Documents dealing with English pirates and the fortification of the west coast of Yucatán in the 1670s.

12. Documents relating to the province of Acalan-Tixchel in Campeche for the sixteenth and seventeenth centuries.
13. Papers regarding Spanish missionary activities in Chiapas in the late sixteenth century.

An inventory of the Tozzer Library holdings was published by Weeks (1987).

APPENDIX 6

BIOGRAPHICAL NOTES ON CONTRIBUTORS

The biographical summaries in this appendix include only those individuals who have authored a contribution in one of the *Year Books*.

Eleanor B. Adams (historian). A collaborator with France V. Scholes, Adams served as editor of the *New Mexico Historical Review* in Santa Fe from 1964 to 1975. She wrote extensively on the early colonial and ecclesiastical history of the Maya as well as on the American Southwest and Southern California.

Robert McC. Adams (1926–, archaeologist). Educated at the University of Chicago (Ph.B., 1947; M.A., 1952; Ph.D., 1956), Adams served on the faculty of the University of Chicago (1955–1984) and was director of the Oriental Institute (1962–1968). From 1984 to 1994 he was secretary of the Smithsonian Institution and served on the faculty of Johns Hopkins University. He has done regionally oriented archaeological studies in Iraq, emphasizing the analysis of settlement patterns, and written extensively on the role played by

irrigation, warfare, and ecological diversity in the evolution of the earliest states.

Monroe Amsden (archaeologist). A native of Farmington, New Mexico, as a boy and young man he worked for Neil Judd at Chaco Canyon, where his tasks included pottery sorting and classification with Frank Roberts. In 1925 he went with Alfred Kidder and Earl Morris to Canyon de Chelly as part of an archaeological party from the Peabody Museum (Woodbury 1993:66).

Manuel J. Andrade (1885–1941; linguist). Born in Spain, Andrade was educated at the Instituto Regional of Coruña, and came as a young man to the United States, where he held various positions as a teacher of Romance languages. Becoming interested in the scientific aspects of linguistics, he studied under Franz Boas and received his doctorate from Columbia University in 1929. The following year he accepted a joint appointment as associate professor at the University of Chicago and staff investigator of the Carnegie Institution. Half

of Andrade's time was devoted to teaching advanced students in linguistics and half to fieldwork and research on the languages of the Maya stock. He made many trips to Mexico and Guatemala, amassing enormous amounts of material concerning Yucatecan Maya, Huastec, Quiché, Tzutujil, Cakchiquel, Pokoman, Mam, and other tongues. In the course of this work he developed remarkably effective means for the mechanical recording of speech.

E. Wylllys Andrews IV (1916–1971; archaeologist). Educated at Harvard University (A.B., 1938; Ph.D., 1942), Andrews conducted archaeological investigations of the northern Maya lowlands, including the excavation and restoration of Dzibilchaltún. A collection of over 900 black-and-white photographs by Andrews from Yucatán are at the National Geographic Society in Washington, D.C. (Ruz Lhuillier 1973; Stirling 1973).

Robert H. Barlow (1918–1951; ethnohistorian). Barlow was born in Leavenworth, Kansas, and educated at the Kansas City Art Institute and San Francisco Junior College. He received his B.A. in anthropology from the University of California, Berkeley, in 1941 and taught at Universidad Nacional Autónoma de México and Universidad de las Américas (Mexico City College). His research interest emphasized Mexican anthropology, especially the ethnohistory and ancient history of Mexico. Barlow founded the journal *Tlalocan* (Bernal 1951a, 1951b; Dibble 1951; Harcourt 1951; McQuown 1951; Monjaras-Ruiz and Limon 1996; Smisor 1952).

Heinrich Berlin (1915–1988; archaeologist). At the same time that Tatiana Proskouriakoff was working on a dynastic history of Piedras Negras, Berlin, a German-born investigator living in México City, identified a series of signs that he termed *Emblem Glyphs*, the names for actual city-states (Riese 1988, 1989).

Frans Blom (1893–1963; archaeologist). Born in Copenhagen, Blom excavated at Pueblo Bonito in the American Southwest and conducted fieldwork in southern Mexico (1923, 1925, 1930), Guatemala (1924, 1928, 1937), and Honduras (1935). His manuscripts may be found at the Latin American Library, Tulane University, and the Bancroft Library, University of California, Berkeley (Brunhouse 1976; Guthe 1963b; Luján Muñoz 1964; Termer 1964b, 1964c, 1965; Leifer, Nielsen, and Reunert 2002).

John S. Bolles (1905–1983; architect). Bolles obtained his B.A. degree in engineering from the University of Oklahoma in 1926 and graduated from Harvard with an M.A. degree in architecture in 1932. He worked as a structural engineer in Oklahoma and as an archeolo-

gist for the Oriental Institute of the University of Chicago on the excavations at Persepolis, the ancient capital of Persia, and also for the Carnegie Institution of Washington on a comprehensive study of Chichén Itzá. Many years later he assembled that work into a book titled *Las Monjas: Major Pre-Mexican Architectural Complex at Chichén Itzá*, published by the University of Oklahoma Press in 1977. Bolles is best known for the design of Candlestick Park in San Francisco, on which construction began in August 1958.

George W. Brainerd (1909–1956; archaeologist). Educated at Lafayette College (B.S., 1930) and Ohio State University (M.S., 1935; Ph.D., 1937), Brainerd participated in a University of Pennsylvania–Boston Museum of Fine Arts Joint Expedition to Persia in 1934. Between 1939 and 1942 he was an archaeologist for the Carnegie Institution of Washington and excavated at Oxkintok in 1940 and at Yaxuna, Dzibilchaltún, Acanceh, Mayapan, Ticul, Dzan, and Mani in 1942. He taught at University of California at Los Angeles and was affiliated with the Southwest Museum. He conducted fieldwork in Iran (1929–1934), Arizona (1935–1938), Tennessee (1939), and Yucatán (1940, 1943) (Hoijer and Beals 1956; Rosaire 1956; W. Smith 1956).

Kirk Bryan (1888–1950; geologist). Educated at the University of New Mexico (B.A., 1909) and Yale University (Ph.D., 1920), Bryan's professional life began in 1912 as an aide in the U.S. Geological Survey, where he rose to senior geologist by 1926. He served as visiting lecturer in physiography at Harvard University in 1924–1925, was appointed assistant professor in 1926, and full professor in 1943. Bryan's scientific reputation is based primarily on his research on arid-region landforms and processes, conducted largely in the southwestern United States. He was also a noted leader in the geology and dating of archeological sites (Larsen 1951).

William R. Bullard (1926–1972; archaeologist). The son-in-law of Oliver G. Ricketson, Bullard was educated at Harvard University (Ph.D., 1959) and had an extremely active career as a field archaeologist. After researching property walls within the site of Mayapán in the early 1950s, Bullard worked in the Belize River valley (1954–1956), at Altar de Sacrificios (1959–1960) and Topoxté in Guatemala, and at Baking Pot and San Estevan in Belize. His final research was at Macanché in the Petén region of Guatemala where Bullard examined the duration of the Postclassic occupation after the Classic-period Maya collapse (Willey 1973, 1988h).

Pedro Carrasco Pizana (1921– ; ethnohistorian). Carrasco was born in Madrid and educated at Escuela

Nacional de Antropología (1945), Universidad Nacional Autónoma de México (M.A., 1945), and Columbia University (Ph.D., 1945). An ethnographer and ethnohistorian, he conducted research among Nahua and Otomí, Tarasco, Mixe, Chontal de Oaxaca, Quiché, and Cakchiquel. He taught at the State University of New York at Stony Brook and was later senior research associate at Brandeis University.

Jean Charlot (1898–1979; artist). Born in Paris, Charlot was the great-nephew of Eugène Goupil, a collector of pre-Hispanic Mexican antiquities. He was educated at the Lycée Condorcet and studied informally at the École des Beaux-Arts in Paris. Charlot was commissioned as staff artist for the Carnegie Institution of Washington expedition to Chichén Itzá, Yucatán (1926–1928). Charlot's archaeological renderings and descriptions were also included in *A Preliminary Study of the Ruins of Coba, Quintana Roo, Mexico* (Thompson, Pollock, and Charlot 1932). After the completion of the Yucatán project in 1928 Charlot accepted a series of academic and other positions. In 1949 he accepted a position as professor of art at the University of Hawaii and retired as senior professor emeritus in 1966.

Ann Chowning (1929–; archaeologist). Chowning received her Ph.D. in anthropology from the University of Pennsylvania. Her doctoral thesis was based on her 1954 fieldwork with the Lakalai people of West New Britain Province, Papua New Guinea. During her lengthy career she maintained an interest in social organization, gender issues, and cargo cults in Melanesia.

Guy N. Collins (1872–1938; botanist). Collins, of the U.S. Department of Agriculture's Bureau of Plant Industry, traveled to Mexico and Guatemala on teosinte hunts, discovered or rediscovered a number of teosinte populations, brought seed back to the United States, and began to study teosinte and its hybrids with maize. He had a central role in raising the interest level in teosinte among maize geneticists in the United States through a series of seminal papers.

John H. Denison (1906–1943; archaeologist). Denison owned and operated a ranch in Bighorn, Wyoming, but much of his life had been spent in both archaeological and anthropological studies. Denison died of pneumonia during World War II shortly after arriving as an American Field Service ambulance driver at Gambut, North Africa.

John M. Dimick (archaeologist). Dimick was a professional engineer who became interested in archaeology and began to organize digs and restore ruins in various parts of the world. He was the author of *Epi-*

sodes in Archaeology: Bit Parts in Big Dramas (Barre, MA: Barre Publishers, 1968).

Ralph A. Emerson (1912–1979; botanist). Emerson, a pioneer in experimental mycology, was educated at Harvard University (M.A., 1933, 1934; Ph.D., 1937). After a year at Harvard as a Harvard research fellow, he joined the faculty at Berkeley in 1940 and spent his entire academic career at the University of California at Berkeley.

Carl E. Guthe (1893–1974; archaeologist). Guthe was educated at the University of Michigan (B.S., 1914) and Harvard University (M.A., 1915; Ph.D., 1917). He served as associate director, Andover Pecos Expedition, Phillips Academy (1917–1920); research associate, Carnegie Institution of Washington (1920–1922); associate director (1922–1929) and director (1929–1943), University Museum, University of Michigan; and director, New York State Museum (1944). He conducted field research in New Mexico (1916–1920); Belize and Guatemala (1920–1922); and the Philippines (1922–1925) (Griffin and Jones 1976; Woodbury 1993:75).

Asael T. Hansen (1903–; linguist). Hansen was educated at Utah State University (B.S.) and University of Wisconsin (Ph.D., 1930). He was a field worker for the Carnegie Institution of Washington and later taught at Michigan State University and the University of Alabama. His research interests included urbanization, urban-rural relationships, Yucatán, Japanese minorities, and West Coast evacuee camps.

Joseph A. Hester (geographer). Hester was educated at University of California at Los Angeles (A.B., 1949; Ph.D., 1954). Published with Ralph L. Beals on land-use patterns among California Indians.

William N. Irving (1927–1987; archaeologist). Irving taught at University of Toronto, and his research interests included the archaeology and ethnology of Yukon Territory and the Mackenzie and Keewatin districts of Canada, and Early Man studies in northern North America (Julig and Hurley 1988a, 1988b).

Jesse D. Jennings (1909–1997; archaeologist). Educated at Montezuma College, New Mexico (B.A., 1925) and the University of Chicago (Ph.D., 1943), Jennings served as an archaeologist for the Carnegie Institution of Washington at Kaminaljuyú in Guatemala and later taught at the University of Utah.

James H. Kempton (botanist). While employed by Bureau of Plant Industry, U.S. Department of Agriculture

in 1911, G. N. Collins and Kempton found the first clearly recognized linkage in corn, discovering that the gene for the waxy endosperm is linked to the gene aleurone color. This discovery led to the concept of crossing-over, in which segments of homologous chromosomes break and exchange genes creating genetic recombinations.

Alfred V. Kidder (1885–1963; archaeologist). Born in Marquette, Michigan, Kidder entered Harvard University to train as a physician. During summer 1907 he changed his career goal to archaeology after a summer field experience under Edgar Lee Hewett in the American Southwest. He received his bachelor's degree in 1908 and his Ph.D. in 1914 with a dissertation that put forward a new methodology for the study of prehistoric Southwestern pottery. From 1914 to 1915 Kidder collaborated with Samuel J. Guernsey to formulate the archaeological chronology of the southwestern United States. From 1915 to 1925 Kidder maintained one of the longest field archaeological projects in the Southwest at Pecos Pueblo, New Mexico. The principle of geologic stratigraphy was practiced at Pecos Pueblo, and Kidder used this principle to tie other archaeological sites of the area to Pecos Pueblo in time and space. During his years at Pecos, Kidder used a multidisciplinary approach to field archaeological studies by involving many specialists from other disciplines in the resolution of archaeological problems. Pecos Pueblo was a field method training ground for students such as Frans Blom, Carl Guthe, Samuel K. Lothrop, George C. Vaillant, and Robert Wauchope. In 1929 Kidder became chairman of the Carnegie Institution of Washington's Division of Historical Research effort in Maya archaeology. He introduced his "pan-scientific" or multidisciplinary approach to the study of Maya archaeology. Aerial archaeology began as a method at this time as Kidder and Charles A. Lindbergh worked jointly on the discovery of Maya sites. Kidder's best known Maya investigations were at Kaminaljuyú in the Guatemala highlands. In 1950 Kidder retired from the Carnegie Institution as the institution's focus of support began to move away from the social sciences and humanities and toward the hard sciences. The Alfred Vincent Kidder Papers, on deposit in the Harvard University Archives, are a primary resource for charting the development of archaeology in the Southwest and Mesoamerica (Caso 1963; Givens 1989, 1992a; Greengo 1968; Guthe 1963a; Judd 1965; Ruz Lhuillier 1963; Samayoa Chinchilla 1965; Termer 1964a; R. Thompson 1991; Wauchope 1965a; Willey 1988a; Woodbury 1973, 1993).

J. O. Kilmartin (surveyor). Using traditional surveying equipment and cartographic techniques of the period,

J. O. Kilmartin, John P. O'Neill, and Karl Ruppert produced the Carnegie map of Chichén Itzá. The J. O. Kilmartin Papers are presently housed at the Boundary End Archaeology Research Center in Barnardsville, North Carolina.

John M. Longyear (1914–; archaeologist). Educated at Cornell University (B.A., 1936) and Harvard University (Ph.D., 1940), Longyear investigated Maya archaeological sites in Honduras and El Salvador, and later taught at Colgate University.

Cyrus Lundell (1907–1993; botanist). While still an undergraduate at Southern Methodist University, Lundell accepted a position as assistant physiologist at the Tropical Plant Research Foundation in Washington, D.C. He served as a field worker in Belize, undertaking tapping experiments on the sapodilla (*Achras zapota*) tree for the U.S. chewing gum industry. In 1931, while traveling deep into unmapped Campeche, he located Calakmul with its sixty-five stela. Lundell directed botanical expeditions to Guatemala, Mexico, and Belize for the Carnegie Institution of Washington, and discovered sixteen Maya archaeological sites. In 1981 he was awarded the Order of the Quetzal by the Guatemalan government (Lipscomb 1995:67).

Paul S. Martin (1898–1974; archaeologist). Educated at the University of Chicago (Ph.B., 1923; Ph.D., 1929), Martin excavated in Wisconsin (1925), Illinois (1927), Yucatán (1926–1928), Colorado (1928–1934, 1937–1938), and New Mexico (1939, 1941, 1946, 1947). Martin was employed by the Field Museum of Natural History from 1929 until his death in 1974. For nearly thirty years (1935–1964) he served as chief curator in the Department of Anthropology (Longacre 1976).

Norman A. McQuown (1914–; linguist). McQuown was educated at the University of Illinois (B.A., 1935; M.A., 1936) and Yale (Ph.D., 1940), and later taught at the University of Chicago. His research interests included descriptive grammar, texts, and lexicon in Mayan languages (especially Huastec, Yucatec, Mam, and Quiché), Classical Nahuatl, and Turkish

Sylvanus G. Morley (1883–1948; archaeologist). Morley received a degree in civil engineering from the Pennsylvania Military College in 1904 and a B.A. (1907) and M.A. (1908) from Harvard University. He never pursued a doctorate but received an honorary doctorate from the Pennsylvania Military College in 1921. He spent from 1910 to 1912 at Quiriguá, Guatemala, where the restoration work, much of it overseen by Morley, was the first to be undertaken at any Maya site. In 1914 the Carnegie Institution of Washington

accepted Morley's proposal to excavate Chichén Itzá, Yucatán. Morley headed the Carnegie program until 1929, when Alfred Vincent Kidder was named the director of the Division of Historical Research. Like Alfred Maudslay and Teobert Maler before him, Morley undertook daring expeditions into the remote jungles of Mexico and Guatemala to record new sites and monuments. His greatest single achievement in exploration came in 1916 with the discovery of Uaxactún; the site yielded some of the most important archaeological findings in pre-World War II Maya research. Morley was at heart an epigrapher. His epigraphic research led to the decipherment of a variant of the tun (360-day period) glyph, the end-of-tun glyph, and the five-tun and ten-tun anniversary glyphs. He established the general lunar significance of the Supplementary Series (a set of glyphs following the major calendrical glyphs that lead off many Maya descriptions). Morley is less well known, however, for breakthrough epigraphic discoveries than for amassing an enormous database of primarily calendrical inscriptions through his relentless field explorations. Morley's lectures and articles, especially those appearing in the 1920s and 1930s in *National Geographic* with dramatic scenes in brilliant color, stimulated public interest as never before. He was appointed director of the School of American Research in 1947 and, at the time of his death in Santa Fe, had planned to assume that post on retirement from the Carnegie Institution. Morley's personal papers related to his Carnegie years are at the Peabody Museum of Archaeology and Ethnology, Harvard University (Black 1990a, 1990b; Brunhouse 1971; Carnegie 1923; Carpenter 1950; Givens 1992a; Harris and Sadler 2003; Harrison 1950; Kidder 1930a, 1948, 1950, 1959; Morley 1943; Recinos 1948; Roys and Harrison 1949; Ruz Lhuillier 1948, 1950; R. Smith 1949; J. Thompson 1949; Villacorta Calderon 1932, 1939; Wauchope 1965b).

Ann Axtell Morris (1900–1945; artist). Morris graduated from Smith College in 1922 and then studied in France with the American School of Prehistoric Research. From 1923 onward she collaborated with her husband, Earl H. Morris, on archaeological work in the Southwest and Yucatán. She copied all paintings at Chichén Itzá and later wrote two popular books on her experiences (A. Morris 1931; E. Morris, 1931; Tisdale 1993; Woodbury 1993:16).

Earl H. Morris (1889–1956; archaeologist). Morris conducted excavations in southwestern Colorado, northwestern New Mexico, Arizona, Chichén Itzá, and Guatemala. He entered University of Colorado in 1908 after working his way through high school as an expert fireplace and chimney mason. He left the university

temporarily in 1912 to go to Quiriguá with Edgar Hewitt and Sylvanus Morley before receiving his degree in 1914 (University of Colorado, M.A., 1916; D.Sc., 1942). That winter he returned to Quiriguá with Neil Judd and Jesse L. Nusbaum to make glue molds of the large sculptured monuments for the Panama-California Fair in San Diego. From 1924 to 1929 he worked winters in Yucatán and summers in the Southwest. In 1929 he left Carnegie and concentrated on the Southwest. The Earl Morris Papers are at the University of Colorado, Boulder (Burgh 1957; Kidder 1957; Woodbury 1993:46).

Lila M. O'Neale (1886–1948; textile specialist). During her lifetime, O'Neale was acknowledged as the foremost expert on prehistoric textiles of the indigenous Americas. A graduate of Leland Stanford Junior University, O'Neale worked as a teacher in the Oakland Public Schools from 1910 to 1913). She continued her education at the Teacher's College, Columbia University, and in 1926 enrolled at the University of California, Berkeley, as a graduate student in household arts. It was there that O'Neale collaborated with Alfred Kroeber, who had just returned from fieldwork in Peru with textiles excavated for the Field Museum in Chicago. Kroeber recognized the quality of O'Neale's scholarship and professionalism and suggested in 1929 that she study the material culture of the Hupa, Yurok, and Karok peoples of northern California. Her dissertation, *Yurok-Karok Basket Weavers*, was published in 1932 in the University of California Publications in American Archaeology and Ethnology Series. The O'Neal Papers are deposited in the Department of Textile Design at University of California, Berkeley (Harrison 1948; Schevill 1986, 1988).

John P. O'Neill (archaeologist). O'Neill served as cartographer at Chichén Itzá and surveyed several other sites during the 1932–1933 field season. The papers of John P. O'Neill are deposited at the Yucatec Maya Program of the Duke–University of North Carolina Program in Latin American Studies.

Alexander Pogo (1893–1950?; astronomer). Pogo compared dates in the Dresden Codex with actual observable eclipses in the Maya region, concluding that the tables dealt with lunar, not solar, eclipses.

Harry E.D. Pollock (1901–1982; archaeologist). Pollock was born in Salt Lake City and attended the Thatcher School in Ojai, California, the Hill School in Pottstown, Pennsylvania, and Harvard University (B.A., 1923; M.A., 1930; Ph.D., 1936). Pollock conducted the CIW Architectural Survey in the Maya region and served as the final director of the archaeology program (H.E.D.

Pollock 1980; Willey 1983, 1988e).

Tatiana Proskouriakoff (1909–1985; archaeologist). Proskouriakoff received her B.S. in architecture from Pennsylvania State University in 1930. During the Depression she worked for Linton Satterthwaite at the University of Pennsylvania Museum and in 1936 joined the University Museum expedition to Piedras Negras. Through her later analysis of patterns of dates and glyphs at Piedras Negras she was able to identify a sequence of seven rulers for a span of almost two hundred years. She also showed that these texts indicated rites of passage and major feats of these rulers. For her discovery that ancient Mayans were recording their history, Proskouriakoff was awarded the Alfred V. Kidder Medal in 1962. She was given honorary degrees from Tulane University and Pennsylvania State University in the 1970s, and in 1984 she received the Order of the Quetzal, the highest honor awarded to a foreigner by Guatemala. She retired as Curator of Maya Art at the Peabody Museum of Archaeology and Ethnology, Harvard University (Berlin 1985; Graham 1990; Homenaje 1986; Rivera 1987; Rosas 1988; Villela 2000).

Robert Redfield (1897–1958; ethnographer). Educated at the University of Chicago (B.A., 1920; J.D. 1921; Ph.D., 1928), Redfield began teaching at the University of Chicago in 1928. He was later professor of anthropology and dean of the Social Science Division. His field research in Mexico in the 1920s resulted in *Tepoztlán* (1930), a pioneer case study of a folk community. As research associate (1930–1947) at the Carnegie Institution, he directed anthropological investigations in Yucatán and Guatemala and evolved the concepts of folk society and folk culture. In later years he turned increasingly to the comparative study of civilizations. The Redfield papers are in Special Collections, University of Chicago Library (Eggan and Miner 1959; Eidheim 1959; Guiteras Holmes 1961; Hansen 1976; Leslie 1976; Mendelson 1981; Miner 1959; Singer 1959a, 1959b, 1976).

Oliver G. Ricketson (1894–1952; archaeologist). Ricketson studied anthropology at Harvard University (B.A., 1916) but changed to medicine after he returned from World War I. He never completed his medical degree, and in 1920 he moved to Flagstaff and then to Kayenta, about thirty kilometers south of the Utah border, where he lived with John and Louisa Wetherill at their trading post. For a while Ricketson worked in Marsh Pass with the archaeologist Samuel J. Guernsey of Peabody Museum. In 1921 Ricketson met Sylvanus Morley and went with him to Yucatán as a mule skinner, returning the next year as a cartographer and draftsman. In 1923 he again worked for Morley, first at Chichén Itzá and

then at Uaxactún in 1926, where he took charge of the work. Ricketson's study of Uaxactún was the basis for his doctoral dissertation submitted at Harvard in 1934 (Lothrop 1953; Woodbury 1993:55).

Henry B. Roberts (1904–1960; archaeologist). Roberts was involved in the study of Yucatán Maya ceramics between 1931 and 1936. He conducted excavations at Uxmal, Sayil, Labná, Kabah, Sabacché, Yaxuna, Coba, and Holactún. After military service in World War II he joined Prentice-Hall as a staff editor and remained in publishing until his death (Woodbury 1993:102).

Ralph L. Roys (1879–1965; ethnohistorian). Roys was educated at the University of Michigan (Ph.B., 1900) and Whitman College (L.H.D., 1936) and spent his entire career in the lumber business. A chance meeting with William E. Gates in California in 1915 gave Roys access to a number of documents, including the books of Chilam Balam and Ritual of the Bacabs. When Gates was made director of the Department of Middle American Research at Tulane University, he arranged a part-time position for Roys (1924–1930), who was able to continue supervision of the family lumber interests. After publication of his *The Ethno-Botany of the Maya* in 1931, Roys joined the staff of the Carnegie Institution on a part-time basis. He often explored remote parts of Yucatán, either on foot or muleback, trying to trace the boundaries of the old provinces into which Yucatán had been divided before the Spanish conquest. The Roys Papers are at University of Washington Libraries, Special Collections (Ventur 1978).

Karl Ruppert (1895–1960; archaeologist). Born in Phoenix and educated at the University of Arizona (B.S., 1920), George Washington University (M.S., 1925), and Harvard University (M.A., 1928), Ruppert conducted fieldwork for the Carnegie Institution of Washington in Campeche (1932–1938), Bonampak (1946), Veracruz (1937), Chichén Itzá (1924–1937, 1942, 1945–1947, 1952), and Mayapán (1951–1954) (Lambert 1961; Woodbury 1993:77).

William T. Sanders (archaeologist). Educated at Harvard University (Ph.D., 1957), Sanders is currently Evan Pugh Professor Emeritus of Anthropology at Pennsylvania State University. His major contribution has been his development of cultural ecology as an explanatory tool for understanding the development of prehistoric urbanism. His use of these concepts in his extensive archaeological research in the Teotihuacan Valley of central Mexico, Kaminaljuyú in the Guatemala highlands, and Copán in western Honduras has provided major insights into the functioning of prehistoric Mesoamerica.

Anna O. Shepard (1903–1973; ceramicist). Educated at the University of Nebraska (1926) with graduate study at the University of New Mexico (1929), Claremont College (1930), New York University (1938), Massachusetts Institute of Technology (1940), and the University of Colorado (1943), Shepard was a pioneer in the technical analysis of pottery from archaeological contexts in the American Southwest and Mesoamerica. The Anna O. Shepard archive (48 linear feet) is located at the University of Colorado Museum (Bishop 1991; Rands 1991).

Edwin M. Shook (1911–2000; archaeologist). Shook studied at the Drexel Institute (1930–1931), Columbia Institute of Technology in Washington, D.C. (1932–1933), George Washington University (1933–1934), and Harvard University (1937–1940). He was originally hired by the Carnegie Institution of Washington as a draftsman in its Washington, D.C., office but was eventually developed into a field archaeologist. After his work at Mayapán he directed excavations for the University of Pennsylvania Museum at Tikal (Love 2002; Popenoe de Hatch 2000; Shook 1990, 1998).

A. Ledyard Smith (1901–1985; archaeologist). Smith, a 1925 graduate of Harvard College, worked for the Carnegie Institution of Washington from 1927 until 1958 at Uaxactún, the Guatemala highlands, and Mayapán, and later for the Peabody Museum of Archaeology and Ethnology at Harvard University at Altar de Sacrificios and Seibal. In 1968 he was awarded the Order of the Quetzal by the government of Guatemala (Willey 1988c).

Robert E. Smith (1899–1983; archaeologist). The elder brother of A. Ledyard Smith, Robert Smith received his primary and secondary education while living in Switzerland and Massachusetts, and graduated from Harvard University in 1922 with a degree in history and romance languages. He became involved in archaeology when he accompanied Ledyard to Uaxactún in 1929. He accepted a position with the Carnegie Institution of Washington and spent the next twenty years as the Carnegie's Guatemala City representative. Smith ended his career as a research associate of Middle American Ceramics at Harvard University's Peabody Museum from 1965 to 1968, and as an honorary research associate of that institution until his death in 1983. The Robert Eliot Smith Papers are at Special Collections and University Archives, Malcolm A. Love Library, San Diego State University (*New York Times*, October 24, 1967, p. 44).

Morris Steggerda (1900–1950; geneticist). Steggerda received his B.A. from Hope College in 1922, and his

M.A. and Ph.D. from the Department of Zoology, University of Illinois (1923, 1928). In 1930 he was hired by the Carnegie Institution of Washington at the Cold Spring Harbor Laboratory. His professional interests included the growth of Maya, Navajo, Black, and Dutch children, and the development of anthropometric instrumentation. Between 1944 and 1950 he taught at the Hartford Seminary Foundation in Connecticut. His personal papers, including anthropometric records collected by the Carnegie Institution of Washington and photographs, measurements, hair samples, palm prints, and dental records, are at the National Museum of Health and Medicine, Armed Forces Institute of Pathology, Washington, D.C. (Count 1951).

Gustav Stromsvik (1901–; carpenter, mechanic, archaeologist). A former Norwegian sailor, Stromsvik participated in fieldwork at Chichén Itzá, directed excavations at Copán (1935–1942), and did stela restoration at Quiriguá.

Sol Tax (1907–1995; ethnographer). Educated at University of Wisconsin, Madison (Ph.B., 1931) and University of Chicago (Ph.D., 1935), Tax conducted early fieldwork in Algeria (1930) and New Mexico (1931). Employed by Carnegie Institution of Washington between 1934 and 1948, he conducted ethnographic fieldwork at Santo Tomas Chichicastenango (1934–1935, 1938–1939), Panajachel (1935–1937) in Guatemala, and Zinacantan (1943–1944) in southeastern Mexico. He was later professor of anthropology at the University of Chicago. His field notes are deposited at University of Chicago Library (Memoriam 1995; Stanley 1996).

Donald E. Thompson (1931–; archaeologist). The son of J. Eric S. Thompson, Thompson focused on Inca archaeology and ethnohistory. He conducted archaeological fieldwork in Peru on the north-central coast at Casma and Huarmey and in the eastern Andes along the Upper Marañón River. He was professor of anthropology at the University of Wisconsin, Madison.

J. Eric S. Thompson (1898–1975; archaeologist). Educated at Winchester College and Cambridge University (1922–1925), Thompson participated in the Carnegie Institution of Washington excavations at Chichén Itzá (1926). He served as assistant curator at the Field Museum of Natural History (1926–1934), and in 1935 joined the Carnegie Institution of Washington (Barthel 1979; Graham 1976; Hammond 1977, 1978; León Orozco 1979; Piña Chan 1977; Ruz Lhuillier 1976–1977; Satterthwaite 1975; Willey 1979).

George C. Vaillant (1901–1945; archaeologist). Vaillant was educated at Harvard University (A.B., magna cum

laude, 1922; M.A., 1925; Ph.D., 1927) and his unpublished but widely circulated doctoral dissertation *The Chronological Significance of Mayan Ceramics* was a pioneering work on the chronology and cultural history of the Maya. Between 1927 and 1941 Vaillant served as curator of Mexican archaeology at the American Museum of Natural History in New York City. In addition, Vaillant taught part time in the anthropology departments at Columbia, Yale, and New York universities. He carried out archaeological expeditions in the Southwest (1921–1922, 1922–1925), Egypt (1923–1924), and Central America (1926, 1928–1936). In 1941 he took the position of director of the University Museum at the University of Pennsylvania. Besides working as museum director, Vaillant was a part-time professor of anthropology on the graduate faculty at the University of Pennsylvania. During World War II, Vaillant served as the first cultural attaché in the American embassy in Lima, Peru (Bleeker 1945; Caso 1946; Kidder 1945; Strong 1945; Willey 1988d).

Alfonso Villa Rojas (1906–1998; ethnographer). Villa Rojas was born in Mérida, came to Chan Kom as a teacher in 1927, and lived there until December 1931. He met Robert Redfield when the latter first visited Chan Kom in 1930. Villa Rojas went to the University of Chicago from 1933 to 1935. Villa Rojas held many public offices in which he was responsible for apply-

ing anthropological knowledge to the improvement of the social conditions of the Indians. He directed a program of ethnographic studies of the Indians affected by the construction of a hydroelectric dam on the Papaloapan River (1949–1952). He assumed the directorship of the Centro Coordinador Indigenista Tzeltal-Tzotzil in San Cristóbal de las Casas (1955). He was director of anthropological research at the Interamerican Indian Institute (1967–1970) and sub-director of the Instituto Indigenista Nacional (1970–1976) (Bricker and Vogt 1998).

Robert Wauchope (1909–1979; archaeologist). Wauchope was educated at the University of South Carolina (B.A., 1931) and Harvard University (M.A., 1933; Ph.D., 1942). He taught at University of Georgia (1938–1940), University of North Carolina (1940–1942), and later was head of the Middle American Research Institute, Tulane University. He served as a temporary staff member of the Carnegie Institution of Washington from 1932 to 1936. Alfred Kidder first took Wauchope to the field at the excavation of Forked Lightening Ruin as a college freshman. He joined the Carnegie Institution of Washington (1932–1936) and made major contributions to Mesoamerican archaeology, as well as to the archaeology of the American Southeast (Harrison 1978; King 1978; Pohorilenko 1978; A. Smith 1978; Woodbury 1993:72–73).

APPENDIX 7

INDIVIDUALS ASSOCIATED WITH CARNEGIE INSTITUTION OF WASHINGTON MAYA PROGRAM

- Adams, E. B., historian, 1936–1948
 Adams, J. P., archaeologist, 1915
 Adams, R. M., archaeologist, 1953
 Amsden, M., archaeologist, 1924, 1927, 1928, 1931, 1955
 Andrade, M. J., linguist, 1930–1938
 Andrews, E. W., archaeologist, 1939–1942
 Atwood, R. S., geographer, 1932
 Atwood, W. W., geographer, 1932
 Barlow, R. H., ethnohistorian, 1950
 Barrett, S. A., museologist, 1937
 Barrow, D., archaeologist, 1938
 Bartlett, H. H., botanist, 1931
 Bennett, B. L., medical laboratory technician, 1929, 1931, 1932
 Bequaert, J. C., entomologist, 1929
 Berlin, H., archaeologist, 1953, 1954
 Binney, A., archaeologist, 1946
 Binney, D., archaeologist, 1946, 1947
 Blom, F., archaeologist, 1924,
 Boggs, S. H., archaeologist, 1939, 1940, 1942
 Bolles, J. S., architect, 1931–1934
 Bradshaw, S. L., linguist, 1941–1947
 Brainerd, G. W., archaeologist, 1939–1942, 1949
 Bryan, K., geologist, 1945
 Bullard, W. R., archaeologist, 1952, 1953
 Burgh, R. F., archaeologist, 1941
 Camara Barbachano, F., ethnographer, 1944
 Carpenter, A. W., photographer, 1916
 Carrasco, P., ethnohistorian, 1953
 Chamberlain, R. S., historian, 1932–1942, 1947
 Charlot, J., artist, 1926–1929
 Chowning, A., archaeologist, 1955
 Clarke, S. T., medical researcher, 1934
 Collins, G. N., botanist, 1935, 1937
 Connell, F. H., protozoologist, 1931, 1932
 Cook, O. F., agronomist, 1922
 Cooke, C. W., geologist, 1931
 Cosgrove, Harriet S., conservator, 1937
 Crandall, E. L., agronomist, 1925–1927
 Currie, L. J., archaeologist, 1941
 Curth, W., dermatologist, 1932
 Davidson, W., ethnographer, 1946
 De Harport, D., photographer, 1953
 Denison, J. H., archaeologist, 1932–1934, 1937, 1938
 Dimick, J. M., archaeologist, 1941
 Dios Rosales, J. de, ethnographer, 1938, 1941

- Elliott, D., archaeologist, 1942
 Emerson, R. A., botanist, 1935
 Ennis, M., archaeologist, 1938
 Fite, H., sculptor, 1938
 Franks, R. A., archaeologist, 1926, 1927
 Fry, Edward I., archaeologist, 1955
 Gaige, F. M., biologist, 1931
 Gann, T.W.F., archaeologist, 1916, 1918, 1926
 Gates, W. E., archaeologist, 1920, 1921
 Gillin, J., ethnographer, 1944
 Goodner, K., bacteriologist, 1929
 Goubaud Carrera, A., ethnographer, 1944, 1945
 Guillot, I., mechanic, 1928
 Guiteras Holmes, C., ethnographer, 1944–1946
 Guthe, C. E., archaeologist, 1920–1922
 Hall (Duke), 1936
 Hammond, L. C., mechanic, 1927
 Hanke, L., historian, 1935
 Hansen, A. T., linguist, 1931–1938
 Harrington, J. C., archaeologist, 1936
 Harrison, M. W., editor, 1934–1955
 Held, J., archaeologist, 1917, 1918
 Hester, J. A., geographer, 1952–1954
 Hill, T. J., clinical oral pathologist, 1937
 Holbrook, B. L., secretary/bookkeeper, 1929
 Holmes, W. H., archaeologist, 1916
 Houser, L., artist, 1927, 1928
 Ichikawa, Schouchi, conservator, 1928
 Irving, William, archaeologist, 1954
 Jacobus, D., secretary/bookkeeper, 1931
 Jameson, K., secretary/bookkeeper, 1926
 Jennings, J. D., archaeologist, 1937
 Jessup, M. K., archaeologist, 1922
 Johnson, T. R., surveyor/draftsman, 1928
 Jones, M., surveyor, 1950, 1951
 Kempton, J. H., botanist, 1935–1937
 Kennedy, E.T.P., archaeologist, 1937
 Kerr, A. J., mechanic, 1929
 Kidder, A. V., archaeologist, 1931–1950
 Kilmartin, J. O., surveyor, 1923, 1924, 1929
 Kratz, C., archaeologist, 1936
 Lincoln, J. S., ethnographer, 1941
 Lincoln, W. L., draftsman, 1932
 Longyear, J. M., archaeologist, 1938, 1939, 1946
 Loomis, H. F., agronomist, 1922
 Lothrop, S. K., archaeologist, 1916, 1922, 1932, 1933
 Love, W. A., surveyor, 1923
 Lucas, V., artist, 1937
 Lundell, C. L., botanist, 1933, 1937, 1938
 MacKay, K., nurse/housekeeper, 1927–1929, 1931
 Martin, agronomist, 1922
 Martin, P. S., archaeologist, 1927, 1928
 McBryde, F. W., geographer, 1932
 McQuown, N. A., linguist, 1947–1949
 Morgan, H., archaeologist, 1948
 Morley, S. G., archaeologist, 1914–1946
 Morris, A. A., artist, 1925–1929
 Morris, E. H., archaeologist, 1924, 1925, 1927–1928, 1934
 Murie, A., mammalogist, 1931
 Núñez, J., archaeologist, 1942
 Nusbaum, D., archaeologist, 1935
 O'Neale, L. M., textile specialist, 1936
 O'Neill, J. P., archaeologist, 1932, 1933
 Parris, F. P., archaeologist, 1934
 Patton, R. T., archaeologist, 1937
 Pearse, A. S., biologist, 1936
 Peter, G., museologist, 1937
 Piatt, N. E., secretary/bookkeeper, 1927, 1928
 Pogo, A., astronomer, 1935

GLOSSARY

Adelantado: title conferred on governor of a newly conquered territory or newly established province.

Aguada: water hole or surface pond.

Ahau: literally “lord” or “ruler,” this title was carried by the upper stratum of royal figures, including women; an inherited status.

Alcalde: municipal mayor, judge, or justice of the peace; member of a *cabildo*.

Alcalde mayor: chief executive officer of a town or district composed of several towns.

Alcaldía: office or territorial jurisdiction of an *alcalde*.

Aldea: small village; hamlet.

Alguacil: constable.

Archivo General de Indias: The Archivo, located in Seville, was established by Carlos III in 1785 to collect in one place all documents associated with the Spanish colonization of the Americas. Documents date from the fifteenth through nineteenth centuries. The Archivo General de Indias is operating a massive project to preserve and make accessible the contents

of the 45 million documents and 7,000 maps and blueprints that form the written heritage of Spain’s 400 years in power in the Americas.

Arriero: muleteer.

Atlantean figure: an architectural support in the form of a standing human, identified with the Toltec. Colossal Atlanteans rise on the platform of the pyramid of the Temple of Quetzalcoátl at Tula in central Mexico. Smaller figures supporting stone slabs found at the Temple of the Warriors at Chichén Itzá attest to the influence of the Toltec on Postclassic Yucatán.

Audiencia: administrative and judicial tribunal.

Auto-de-fé: public announcement of the sentences imposed by the Inquisition.

Ayuntamiento: corporation or body of magistrates in cities or towns; municipal government; replaced in nineteenth century by the term *cabildo* in referring to municipal officers.

Bacabs: Maya deities who supported the sky at four corners of the earth.

Baile: dance.

Bajo: low, swampy depressions; a source of water during the summer months in the Petén region of northern Guatemala.

Bak: four hundred

Baktun: Maya time period of 20 *katuns*, 400 *tuns*, or 144,000 days.

Ballgame: a definitive aspect of Mesoamerican civilization. Ball courts were called *tlachtli* by the Mexicans and *pok-ta-pok* by the Maya. They had an I-shaped playing area but varied in size and architecture. Classic-period ball courts generally consisted of raised viewing platforms along the sides, with lower walls sloping inward to the court. Markers were represented by both stone disks flush in the playing surface and *hachas* tenoned in the parallel facing walls, dividing the length of the court into three sections. In the Postclassic period the facing stones became more vertical, with a single stone ring embedded high and centrally in each wall; players scored by placing a rubber ball through the stone ring. Relief-sculptured ball-court panels at Chichén Itzá portray ballgame ceremonies involving human sacrifice.

Barranca: ravine or gorge.

Barrio: section or subdivision of a town.

Batab: civil and military head of a town; later a *cacique*.

Books of Chilam Balam: Post-conquest manuscripts prepared by Yucatec Maya in European scripts, relating traditions and myths, calendrical data, and medicinal recipes of pre-Hispanic origin. Of the eighteen such books extant, most informative are the *Chilam Balam* of Chumayel, Tizimín, Maní, Kaua, Ixil, and the Pérez Codex.

Cabildo: a town council or local government council.

Cacicazgo: at the time of the conquest, a territory controlled by a *cacique*.

Cacique: hereditary indigenous ruler; chief; political leader.

Calendar Round: an interval of 52 vague years computed by the permutation or intermeshing in cogwheel fashion of the 260-day ritual calendar (composed of 20 named days and 13 numbers) with the solar calendar of 365 days (18 months of 20 days each, followed by a final 5-day period).

Calpul: territorially defined sub-community; lineage or clan.

Cantón: region; district.

Carga: load; *carga de hombre*, about 50 pounds; *carga de mula*, about 200 pounds.

Cédula: royal decree or order; document containing such an order.

Cenote: a natural underground reservoir of water, such as occurs in the limestone of Yucatán, Mexico.

Chac mool: life-sized stone figure lying on its back with flexed legs, hands holding a flat receptacle on its stomach, and with head turned to one side. Although first discovered—and misnamed “Red Jaguar,” which is the meaning in Yucatec Maya—at Chichén Itzá, its origin can be traced to the Toltec capital of Tula, in the state of Hidalgo, central Mexico.

Chicleros: woodsmen engaged in the bleeding of the sap sapodilla trees for chicle, an important ingredient for the manufacture of chewing gum. Morley employed *chicleros* to report the locations of archaeological sites in the Petén region.

Chinampa: small garden patch between lagoons.

Chultun: cistern; jar-shaped chambers cut into the limestone bedrock.

Cienaga: a shallow salt-water swamp behind the dunes, which has wide areas of open water with islands of mangrove.

Coati: small raccoon-like arboreal animal of the tropical forest and coastal plains; also known as *pisote* or *tejón*.

Cofradia: religious brotherhood or sodality formed to honor an important patron saint.

Congregación: indigenous community forcibly established by the Crown.

Definitorio: governing council.

Departamento: Each political *departamento* in Guatemala is divided into *municipios*, each of which is typically homogeneous in language and culture and all of which differ from one another in varying degrees. The *municipios* are effective social segments, each tending to be specialized economically, having its own social and religious system, its own distinguishing costume, its own dialect; each has, in addition, a strong feeling of unity and a desire to be endogamous.

Divisas: emblems.

Doctrina: mission district administered by Dominicans or Franciscans; such districts supposedly later became parishes when secular clergy were available to administer them.

Eclipse syzygies: (a) either of two points in the orbit of a celestial body where the body is in opposition to or in conjunction with the sun; (b) either of two points in the orbit of the moon when the moon lies in a straight line with the sun and Earth; (c) the configuration of the sun, the moon, and Earth lying in a straight line.

Ejido: common public land, either of indigenous or Spanish jurisdiction.

Encomienda: grant of indigenous population by the Spanish Crown to an individual, who was entrusted with their Christianization and protection in return for tribute and, sometimes, labor.

Estatuas: wooden idols; statues.

Finca: in colonial times, any rural estate; since the nineteenth century, refers more specifically to cattle ranches or coffee plantations.

Fine Orange: pottery of fine-grained paste, little temper, from the western Maya lowlands, probably near Laguna de Términos, the lower Usumacinta and Grijalva rivers region.

Haab: Maya year of 360 days composed of 18 months of 20 days each. It was followed by a period of five unlucky days, called *Uayeb*, to arrive at a vague year of 365 days.

Hacienda: landed property; plantation devoted to grain production and ranching.

Hematite: an iron oxide used to make red pigment.

H-men: shaman-priest of Yucatec Maya.

Hotun: in Maya temporal reckoning, a quarter *katun*, or five years.

Incensarios: vessel in which resin incense is burned.

Initial Series: Maya calendrical count, so-called because it was the first series of glyphs after the "introducing glyph" inscribed on stela.

Justicia: justice.

Katun: a period of 20 years in the Maya calendar, or 7,200 days.

Kin: smallest unit of the Maya time count.

Ladino: a person not identified as either indigenous or a Spaniard, or an ethnic term for *castas* in late seventeenth and eighteenth centuries; a non-Spaniard seen as Hispanicized.

Laguna: lake.

Lahuntun: a half-*katun*, or a ten-year period in the Maya time count.

Legajo: bundle of papers.

Long Count: A calendrical system for measuring absolute time, devised in Mesoamerica during the Formative (Preclassic) period. The day forms the basic unit (*kin*), thereafter multiplying up into larger units progressing by 20s: *uinal* (20 days), *tun* (360 days), *katun* (7,200 days), and *baktun* (144,000 days). Dates are expressed as units in a five-place notation starting with the largest units. Thus 8.2.4.5.1 means 8 *baktunob*, 2 *katunob*, 4 *tunob*, 5 *uinalob*, and 1 *kin*. The Maya began their counting at a time equivalent to 3114 BC, perhaps marking some mythical event in Maya history. They inscribed their dates in the notation given above as hieroglyphs in which bars represented units of five and dots units of one. The long-count system was replaced after AD 900 by a short-count system in which the *katun* replaced the *baktun* as the largest unit.

Maestro: master, teacher, artisan.

Mangrove: any of several tropical evergreen trees or shrubs of the genus *Rhizophora*, having stiltlike roots and stems and forming dense thickets along tidal shores.

Mano: grinding stone.

Matriculá: register; census.

Mayordomo: superintendent; overseer; custodian; officer of a *cofradia*.

Mecate: surface measure of approximately 20 meters square.

Mestizo: Originally, a person of mixed Spanish and Indian blood in Latin America—the product of *mestizaje*, "racial mixing." The term is now sometimes used to refer more generally to racially mixed persons. Ladino is the common Central American equivalent.

Metate: stone platform upon which a *mano* is used for grinding.

Milpa: field; in Central America and Mexico: a small cultivated field, usually of corn.

Municipio: in highland Guatemala, a political unit more or less resembling a county, but at the same time an ethnic unit, the population of which is most comparable to a "tribe," with its own costume, culture, and identity. Each *municipio* has at least one "town," like a county seat. There are three types of *municipios*: One consists of a town, which may be simply an economic and religious center unpopulated except on certain occasions and surrounding country in which the people live on their scattered farms. A second type is like the first except that there are one or more smaller villages in addition to and dependent upon the town. In the third type, all or most of the people live permanently in the town and leave it when necessary, for short periods, to work the surrounding fields.

Nagualism: belief in the transformation of animal spirits.

New Empire: Obsolete designation applied to the Toltec-influenced Postclassic Period (ca. AD 900–1521) of the northern lowland Maya.

Old Empire: Obsolete designation for the lowland Maya Classic period (ca. AD 300–900); distinguished from New Empire, former name for the period of Toltec influence in Postclassic northern Yucatán.

Olla: Spanish term for a pottery jar with a flaring neck.

Ordenanzas: royal regulations, including those that were devised by visiting judges and members of the *audiencia*.

Padrón: census or tribute list; register of taxpayers.

Peristyle: a series of columns surrounding a building or enclosing a court.

Pipil: a term loosely applied to the language and culture of various Nahuatl-speaking groups whose influence penetrated southern Mesoamerica and Central America from the Mexican highlands.

Plumbate Ware: a pottery characterized by slips of high iron content fired at unusually high temperatures, resulting in a lustrous, glazelike finish, the only Mesoamerican semivitrified ware. Plumbate pottery was widely traded, from Mexico to El Salvador, and its manufacture ceased at the beginning of the Late Postclassic period.

Popolna: community house.

Probanza: evidence or proof.

Pueblo: legally recognized town chartered to elect its own council; village or small town.

Ramada: an open structure of pole and thatch.

Regidor: town councilman in colonial *cabildo*; magistrate.

Relación: relation; report; narration.

Residencia: impeachment.

Sacbé (pl.: *sacbéob*): causeway, or roads, connecting parts of sites, as well as entire sites. The longest *sacbé* known extends 100 km from Cobá to Yaxuná in the Yucatán peninsula.

Sascab: lime gravel.

Sastún: conjuring stone.

Spondylus: red spiny or rock oyster shell (*Spondylus* princes) found in Pacific coastal waters.

Stela: an upright stone slab or column typically bearing a commemorative inscription or relief design.

Supplementary Series: A series, usually of six glyphs, found on Classic-period Maya stela, inserted between the main body of the Initial Series and its final glyph stating the month of the date. This Supplementary Series of glyphs treated the age of the moon on the recorded date, length of this particular lunar month, and other lunar data.

Sweat Bath: a building (*temascalli* in Nahuatl) housing facilities for the steam bath (*temascal*), possibly connected ritually with the ballgame. The buildings usually had a fire area for heating stones over which water was poured to produce steam.

Talpetate: decomposed volcanic tuff.

Tecpan (Nahuatl): government house.

Teosinte: *Euchloenana mexicana*, the nearest known relative of maize; a Mexican fodder grass believed to be a parent plant of maize [*Zea mays* subsp. *Mexicana*].

Título: title, deed, certificate; title of nobility.

Tun: Unit equal to 365 solar days used in the Classic Maya long-count system.

Tzolkin: 260-day calendar.

Usulután Ware: A distinctive Late Preclassic-period pottery found from southern Mexico to northern Nicaragua, most popular in western El Salvador and at Copán, Honduras.

Villa: town enjoying certain privileges by charter; municipal charter.

Visita: tribunal for official inspection of a specified area, or of the work of Crown officials; conducted under the jurisdiction of a Crown-appointed inspector (*visitador*).

Yaxche: term for the ceiba tree (*Bombax pentandra*), sacred to the Maya.

Zoomorph: a representation in the shape or having attributes of an animals; term has been applied to the large, elaborately carved stone boulders found at the Classic-period Maya site of Quiriguá.

FIGURES

1.1.	Map of the Ruins of Mayapán	6	3.1.	Plot of Walls in Southwest Section of Mayapán (see map with <i>Current Report 1</i>)	26
2.1.	The Great Wall and Gates D, G, and H	10	3.2.	Plans of Property Walls	27
2.2.	Gate T, Blocked Gate T, and Gate EE	13	3.3.	Property Walls, Gateways, Lanes, Circle	28
2.3.	Gates AA, B, and O	15	4.1.	Excavations in Structure J-131a, Plan and Section	33
2.4.	The Great Wall of Mayapán	16	4.2.	Excavations in Group J-49, Plans and Sections	34
2.5.	Gate D	17	4.3.	Excavations in Structure J-50a, Plan and Section	35
2.6.	Gate D	18	4.4.	Excavations in Groups J-50 and J-122, Plans and Sections	36
2.7.	Gate T	18	4.5.	Excavations in Structure I-94, Plan and Section	37
2.8.	Gate T	18	4.6.	Excavations in Structures J-131a, I-94, and J-122c	38
2.9.	Blocked Gate T	19	4.7.	Excavations in Structures J-49a, J-49b, and J-50a	39
2.10.	Gate EE	20			
2.11.	Gate AA	20			
2.12.	Gate O	20			
2.13.	Gate O	21			
2.14.	Obsidian Artifacts	22			
2.15.	Obsidian Artifacts	22			
2.16.	Hammerstones (two)	23			
2.17.	Metate	23			
2.18.	Pottery from the Excavations	24			

- 4.8. Artifacts Recovered during Excavation in Groups J-49, J-50, J-131, and I-94 **40**
- 4.9. Artifacts from Midden under East Bench and Back Room of Structure J-50a, Lot A-13 **41**
- 5.1. Plan and Sections of Cenote X-Coton **44**
- 5.2. Sections of Pits and Cave **45**
- 5.3. Sketch of Cenote X-Coton, Looking Northeast, by Tatiana Proskouriakoff **46**
- 5.4. Views of Cenote X-Coton from Exterior **47**
- 5.5. Views of Interior of Cenote X-Coton **48**
- 5.6. Bones, Pottery, and Sculpture **49**
- 6.1. Sketch Map of the Ruins of Chacchob **55**
- 6.2. The Wall, Metates, and Vault Stones **56**
- 6.3. Sketch Plan and Section of Castillo **57**
- 6.4. Architectural Details at Castillo **58**
- 6.5. House Platforms **60**
- 6.6. Views of Wall and of Castillo at Chacchob and Sculpture at Ukum **62**
- 7.1. a. Bellote, Tabasco; Stucco Glyph on Temple Platform, Phase II; b. Bellote, Tabasco; Stucco Medallion on Temple Platform, Phase III; c. Escarcega, Campeche; Plan of Mounds; d. El Tortuguero, Tabasco; Glyphs on Monument 5; e. Atasta, Campeche; Platform, (y) Position of Scattered Bones of Two Adolescents; (z) Position of Isolated Skull of an Adult; f. El Coco, Tabasco; Section of Trench **70**

- 7.5. a. Atasta, Campeche; Statue; b, c. Museum at Ciudad del Carmen, Campeche; b. Jaguar Head; c. Stone Sculpture; d. El Tortuguero, Tabasco; Monument 5; e. Atasta, Campeche; Stone Tablet; f. Champoton, Campeche; Stone Statue in Private Collection; g. El Tortuguero, Tabasco; Monument 3; h. Champoton, Campeche; Stone Sculpture in Private Collection; i. Atasta, Campeche; Stone Sculpture **77**
- 7.6. Archaeological map of Tabasco **82**
- 8.1. Plan of Strs. Q-127 and Q-127a **86**
- 8.2. Sections of Strs. Q-127 and Q-127a **87**
- 8.3. a, b. Str. Q-127, the Portal Vault, from the East; c. Str. Q-127a, from the East; d. Substructure of Q-127a, from the South; e. South Balustrade of Stairway to Str. Q-127a, Showing First Stone of Vertical Block; f. Leg and Head of Stone Figure from Front of Str. Q-127a **88**
- 9.1. Trench North of Str. Q-79 **93**
- 9.2. Small Shrines **94**
- 9.3. Small Shrine, Plan and Sections of Str. Q-71 **96**
- 9.4. "Dance Platform," Str. Q-77 **98**
- 9.5. Circular Platform, Plan and Section of Str. Q-84 **100**
- 9.6. Small Shrines and Statuary **101**
- 9.7. Small Shrine and Associated Censer Pottery, Str. Q-71 **102**
- 9.8. Ceremonial Platforms, Views of Strs. Q-77 and Q-84 **104**
- 9.9. Pottery **106**
- 9.10. Censer Figurines from Trench North of Str. Q-79 **108**
- 9.11. Small Objects **110**
- 10.1. Excavations in Str. Q-119a, Plan and Section **112**
- 10.2. Excavations in Str. R-100, Plan and Section **114**
- 10.3. Excavations in Str. K-52a, Plan and Section **116**
- 10.4. Excavations in Str. K-52c, Plan and Section **119**
- 10.5. Str. Q-119a **120**
- 10.6. Strs. Q-119a, K-52a, and K-52c **121**
- 10.7. Group K-52 **122**
- 10.8. Artifacts Recovered during Excavation in Group K-52 and during Mapping in Square X **123**
- 10.9. Objects Recovered during Excavations in Group K-52 and Str. R-100 **124**
- 11.1. Str. T-70 **128**
- 11.2. Strs. T-70 and T-72, Sections **129**
- 11.3. Str. T-70 and Artifacts **130**
- 12.1. Section of Pit-Trench in Cenote X-Coton **136**
- 12.2. Plan and Sections of Cenote Ch'en Mul **137**

12.3.	Plan and Sections of the Trench and Its East and West Extensions in Cenote Ch'en Mul	138	19.1.	Plans and Sections: Strs. Q-207, Q-208, Q-208a, and Q-209	218
12.4.	Plan of the Cenote in Telchaquillo Plaza and Section of Pit 2	140	19.2.	Str. Q-208 and Pottery Vessels	220
12.5.	Cenote Ch'en Mul	141	19.3.	Artifacts from Q-208	223
13.1.	Plot of Walls in Squares H and I	146	20.1.	Castillo or Temple of Kukulcan (Str. Q-162) and at Chichén Itzá	228
13.2.	Mayapán Boundary Walls	148	20.2.	Sections of Mayapán Castillo	229
13.3.	Map of House Group and Lot (750 S, 620 W) in Square AA	149	20.3.	Str. Q-162	232
13.4.	Stone Circle and Lane Pavement at Mayapán; Boundary Wall at Chichén Itzá	151	20.4.	Strs. Q-77 and Q-162	235
13.5.	Boundary Walls, Stone Circle, Lane, and Cenote Entrance	153	20.5.	Material Recovered from Excavations	236
14.1.	Plan of Strs. Q-58 to Q-60	158	21.1.	Strs. Q-147, Q-148, Q-149, and Q-153	240
14.2.	Strs. Q-58 to Q-60	161	21.2.	Strs. Q-149 and Q-153	242
14.3.	Str. Q-82	163	21.3.	Strs. Q-147, Q-148, Q-149, and Q-153	244
14.4.	Str. Q-95	164	22.1.	Str. Q-97, Plan, Section, Elevation, and Architectural Details	251
14.5.	Str. Q-58	165	22.2.	Str. Q-151, Plan, Sections, and Architectural Details	255
14.6.	Strs. Q-58 to Q-60	167	22.3.	Str. Q-97 and Str. Q-163	256
14.7.	Str. Q-82	169	22.4.	Str. Q-151	258
14.8.	Str. Q-82	170	22.5.	Strs. Q-88a, Q-151, and Q-152	261
14.9.	Str. Q-5 and Material Culture	172	22.6.	Str. Q-151 (l-n, p, u, Str. Q-97; q, Str. Q-88a)	264
14.10.	Material Culture	174	22.7.	Strs. Q-81, Q-97, Q-151, and Q-164	269
15.1.	Plan and Sections of the Northern Terminus of the Sacbe	180	23.1.	Ichmul and Okop, Plans and Sections	273
15.2.	Views of Excavations, Details of Construction, Artifacts	185	23.2.	Ichmul and Okop, Views of Architectural Details and Sculpture	274
16.1.	Plan and Section of Str. Q-214	188	24.1.	Map of Northeast Yucatán, Showing Archaeological Sites Visited, 1954	278
16.2.	Str. Q-214	191	24.2.	Map of Cozumel Island, Showing Archaeological Sites Visited, 1954	279
17.1.	Group A-3, Plan and Sections	195	24.3.	Kantunil Kin, Excavated Mound	281
17.2.	Str. Q-62, Plan, Sections, and Excavations	196	24.4.	El Diez, Plan of Site	281

FOREWORD

MARILYN A. MASSON

Mayapán was the largest, most significant political capital of the Maya world of its time. Its stature as one of the great cities of the ancient world and as a historical landmark site within Mesoamerica is gaining more recognition, particularly with renewed archaeological research at this center over the past two decades. Once characterized as a civilization in ruins that was devoid of great art, Postclassic period Mayapán was naively referred to as “decadent.” Professionals now acknowledge that the significance, success, and regional impact of this (or any other) major city cannot be judged by the types of ruins its builders created, a point made by Malcolm Webb many years ago in his 1964 doctoral dissertation, “The Peten Maya Decline Viewed in the Perspective of State Formation.” The efficient builders at Mayapán and its contemporary centers constructed narrower walls and decorated them with resplendent plaster sculptures and murals that were not necessarily designed to last for five centuries and future appreciation.

Fortunately, some of these works have been partly preserved and hint at what has been lost to the erosional forces of sun and moisture on the hot plains of the northern Yucatán peninsula. Mexico’s Instituto Nacional de Antropología e Historia (INAH) has discovered many of these masterpieces in the site center and has restored that locality for tourism under the direction of archaeologist Carlos Alberto Peraza Lope and his team, led by Pedro Delgado Ku and Barbara Escamilla Ojeda. This work began in 1996 and continues each year. Renewed interest in Mayapán is largely due to these restoration efforts; by receiving an architectural facelift, the site center now reflects more of its former significance and glory.

Among the highlights of new discoveries made by Carlos Peraza Lope’s project include the Hall of Kings, which had life-size anthropomorphic stucco column sculptures of important humans and gods in Mayapán’s history, a stucco facade on the site’s

central Temple of Kukulkan that reflects themes of warfare and sacrifice, a mural on the Hall of the Sun Disks that features panels of priests conjuring figures descending from the heavens, and a mural on the Temple of the Fisherman that depicts a deity figure in the watery underworld surrounded by a water serpent as well as a crocodile and fish impaled by spears. Many ceramic sculptures have also been recovered, most famously, the codaical “monkey scribe” effigy found behind the burial shaft temple known as the “Crematory” (Str. Q-58). Carlos Peraza Lope has published many of these findings in collaboration with Alfredo Barrera Rubio (2001) and with art historian Susan Milbrath of the Florida State Museum, who is engaged in ongoing studies of the city’s art (Aveni, Milbrath, and Peraza Lope 2004; Escamilla, Peraza Lope, and Delgado 1994; Milbrath 2005, 2007; Milbrath and Peraza Lope 2003a, 2003b).

The history of research at Mayapán is outlined by John M. Weeks in the introduction to this volume; another great source is Clifford T. Brown’s Tulane University doctoral dissertation, “Mayapán Society and Ancient Maya Social Organization” (1999:86–109). Brown provides an abridged version of this history online at <http://wise.fau.edu/~ctbrown/Mayapan.html>. The Carnegie Mayapán Project represented an important turning point in Mesoamerican archaeology because of its emphasis on settlement and the study of households in addition to public buildings. The complete map of the city made by Morris Jones (*Current Reports* no. 1) and his team of surveyors was a major investment, and Mayapán still stands as one of the best-mapped ancient cities of Mesoamerica.

In the past eighteen years, research at Mayapán beyond the site center has undergone a resurgence. Clifford Brown’s doctoral studies in the 1990s represented an important return to Mayapán that followed the household-scale investigations there for which A. L. Smith and Karl Ruppert were famous. His work considers the organization of domestic architecture and kin groups as well as the importance of key settlement features, such as cenotes, and he offers innovative statistical studies of artifact types, modes, and distributions (Brown 1991, 1999, 2001, 2005; Brown et al. 2006). These analyses identify key patterns of social and economic organization among clusters of households within the city’s neighborhoods.

From 2001 to 2004, Carlos Peraza Lope, Timothy Hare (Morehead State University), and I began our collaborative research under the auspices of the NSF-supported (SBR-1018919, 1069128) Economic Foundations of Mayapán Project; we returned in 2008 for two more years of fieldwork. This research in the settlement zone has revealed even greater

complexity at Mayapán than previously suspected (Masson 2003; Masson, Hare, and Peraza Lope 2006; Masson and Peraza Lope 2004, 2005, 2007; Masson, Peraza Lope, and Hare 2003; Peraza Lope, Masson, Hare, and Delgado 2006; Peraza Lope, Masson, and Russell 2007; Russell and Dahlin 2007). The results of other collaborative studies are available as well (Galindo Trejo 2007; Gregory 2006; Paris 2008; Serafin 2007; Serafin and Peraza Lope 2007; Uc González 2000; Wright 2007). We have learned that the city comprised a diverse landscape that included a major marketplace, pedestrian pathways leading from the major gates toward the center, and other key landmarks, such as outlying temples, cenotes, public spaces, craft specialist districts, and neighborhoods defined by public buildings (halls and temples) and upper status administrators. Two additional anomalous buildings may represent a school for the nobility (*calmecac*) and a house of commerce. The city’s neighborhoods were provisioned by neighborhood artisans who made pottery and shell and stone tools; other households specialized in animal production, particularly white-tailed deer, which were probably bred and raised in captivity. Occupations of residents were diverse, and craftspeople, domestic servants, religious specialists, warriors, slaves, and farmers have been identified. Despite these diverse productive capacities, Mayapán was dependent on the outside world within and beyond northern Yucatán for raw materials vital to craft industries and also salt, obsidian, and valuables, such as cacao beans and cotton textiles, which were used as currencies in the city’s market. Although the importance of mercantile exchange has long been known for the Postclassic period on a general level, we can now reconstruct the significance and direction of economic dependencies and the effects that these relationships had on the daily lives of members of the commoner and noble classes. Our work also documents a high level of militarism for the city; projectile points and lances are the most common tools at every dwelling and new mass graves and radiocarbon dates point to violence and strife at least a half-century prior to the final collapse around AD 1441. Bradley Russell’s 2008 dissertation, “Postclassic Maya Settlement on the Rural-Urban Fringe of Mayapán, Yucatán, Mexico,” explored settlement beyond the city wall and raises the population estimate for Mayapán from the former figure of 12,000 to up to 17,000 people (<http://Mayapanperiphery.net/>).

Residents of the pueblo of Telchaquillo, located one kilometer north of the site center, have provided the skilled labor for excavating and restoring their monumental center and other archaeological proj-

ects at the city. The site center, owned by INAH, represents less than $\frac{1}{26}$ of the walled portion of the city. Local residents have served as conscientious custodians for the remainder of the settlement zone; more than 96 percent of the city's area is owned privately by dozens of small-scale milpa farmers and ranchers. The settlement zone spans 4.2 square kilometers within the walled portion of the site and up to 500 meters beyond the wall, as Bradley Russell recently determined. Mayapán is unlike many major Maya sites because it is largely unlooted, thanks to a widely shared ethic of conservation that dates at least to the era of the Carnegie investigations, if not before.

Two seminal publications emerged from the Carnegie work at this city: *Mayapán, Yucatán, Mexico* by Harry E.D. Pollock, Ralph L. Roys, Tatiana Proskouriakoff, and A. L. Smith (1962) and *The Pottery of Mayapán* by Robert E. Smith (1971). The 1962 volume by Pollock and colleagues provides an overview of the work performed during this period. This compilation of the Carnegie Institution's *Current Reports* on work at Mayapán represents, in essence, a fairly complete data monograph of investigations performed by Carnegie scholars at that site with information that is simply not available in later publications. These chapters represent a treasure trove of data that has scarcely been mined, containing all of the important details, maps, photographs, and lists of materials recovered from excavations of specific buildings.

Thanks to the efforts of John M. Weeks in assembling this volume of *Current Reports*, scholars no longer have to search libraries' rare books collections (or utilize poorly reproduced photocopies) to find the individual chapters on Mayapán published from 1952 to 1957. The inclusion of a searchable compact-disc version of these publications makes them extremely user-friendly and catapults them into twenty-first-century technology. In the summer of 2003, I spent six weeks going through each report, taking detailed notes on each of the Mayapán *Current Reports* and compiling a database of the lot inventories published within each chapter. Fortunately, with the enclosed electronic version that kind of effort is no longer necessary to access this information. Perhaps one of the most remarkable aspects of the *Current Reports* is the diligence with which excavation lots were reported, described, and inventoried. Although the recovery of materials did not employ the use of screens according to modern conventions, artifacts were collected and reported quite systematically and thus represent a data archive of considerable value. For many lots, the exact number of different kinds of pottery sherds was analyzed

and presented, and many significant photographs of whole vessels, offerings, and non-ceramic artifacts were presented. The lot inventory that I compiled from these reports in 2003 is presented in this volume as an appendix.

Many poorly known but important findings of the Carnegie Project have been long buried in the *Current Reports*. For example, Edwin Shook suggests in *Current Reports* no. 2 that spectators may have witnessed large-scale processions entering the city from Gate O on the west side of the city wall, which was lined with broad stairs. He also noted that the site's principal temple, the Temple of Kukulcan, was clearly visible from this gate when the forest was relatively clear. On the far eastern side of Mayapán, one can also see the Temple of Kukulcan from the Itzmal Ch'en temple (Str. H-17). Donald Thompson's investigations at this outlying temple (H-17) revealed a stone slab altar supported by "Atlantean"-type figures that are reminiscent of Mayapán's predecessor, Chichén Itzá (*Current Reports* no. 28). Other gems in the *Current Reports* include Robert Adams's (*Current Reports* no. 9) initial discovery of a shallow mass grave by the Main Plaza next to Temple Q-80 and the existence of two major palace groups (Groups R-95-99 and R-85-90) with vaulted tunnels running beneath their platforms. Tatiana Proskouriakoff and Charles Temple (*Current Reports* no. 29) conducted a full investigation of R-85-90, providing the best documentation of a Postclassic Maya palace ever undertaken. Other key features at Mayapán that were studied include burial shaft temples Q-58 and Q-95, investigated by Edwin Shook in the site center (no. 14), and their analogs at outlying temple-cenote groups Itzmal Ch'en (no. 34, Ann Chowning) and X-Coton (no. 11, Edwin Shook), as well as a portal vault entrance on the east side of the monumental center (no. 8, Gustav Strömsvik). Many details regarding stratigraphy and variation in architectural and mortuary features are provided in the other *Current Reports*. Although the significance of investigating dwellings ranging from noble residences to modest houses has long been recognized at Mayapán, there is great potential to study them further using the baseline data of this volume.

This compilation of *Current Reports* provides an important supplement to a prior University Press of Colorado publication, *The Carnegie Maya: The Carnegie Institution of Washington Maya Research Program, 1913-1957*, edited by John M. Weeks and Jane A. Hill (2006). This prior work makes available a separate series, that of the Carnegie *Year Book* reports. The *Year Book* entries are short, newsletter-like research reports that provide important summaries of research activities but lack the detailed and

lengthy reporting of architecture, features, and artifacts found in the *Current Reports*. When *Year Book* and *Current Reports* entries overlap, details can differ and the latter series provides a more expansive treatment. The full publication of the Carnegie work at Mayapán is now complete with this publication of the *Current Reports* series.

INTRODUCTION

Between 1914 and 1958 the Carnegie Institution of Washington (CIW) sponsored extensive archaeological, ethnographic, linguistic, historical, and other related investigations in the Maya region of southern Mexico and northern Central America. During these four decades, the CIW was the leader in the field, with monetary and human resources that no university or other research program could match, then or since. The more than 300 publications produced by CIW researchers remain important, indeed essential, resources for modern scholars.

A summary of the development and accomplishments of the CIW program in the Maya region is available elsewhere (Weeks and Hill 2006:1–26) and need not be repeated here. However, some historical background is necessary to properly contextualize the CIW *Current Reports*.

The administration of the Carnegie Institution of Washington supported archaeological research in southern Mexico and northern Central America

for some four decades following its initial approval of a proposal submitted by Sylvanus G. Morley. In 1937 Vannevar Bush replaced John C. Merriam as president of Carnegie Institution of Washington. Bush was a distinguished physicist and dean of the School of Engineering at the Massachusetts Institute of Technology. He was President Franklin D. Roosevelt's primary science advisor during World War II. He also served as chairman of the National Advisory Committee for Aeronautics (1939–1941), chairman of Roosevelt's National Defense Research Committee (1940), and director of the Office of Scientific Research and Development (1941–1947). He provided oversight for some 200 defense-related ventures, including the development of nuclear fission and the Manhattan Project. Under his direction, CIW scientists became heavily involved in war work, and it was Bush's idea of federally funding science that led to the creation of the National Science Foundation in 1950. Not surprisingly, Bush was no

supporter of more humanistic disciplines, including anthropology and archaeology.

As Bush implemented his plan to close the CIW Department of Archaeology, department director Alfred V. Kidder proposed a number of potential final projects. One proposal asked the CIW to underwrite the cost of developing the use of radiocarbon dating for archaeology. This was followed by proposals to undertake a large longitudinal project at the Classic period Maya metropolis of Tikal, as well as a program that would divert attention from the Maya to relationships between the two major centers of civilization in the Americas, Mesoamerica and the Andes. None of these were accepted by the CIW, although excavations at Tikal were soon initiated by the University of Pennsylvania Museum with Edwin M. Shook, a CIW archaeologist, as Field Director. Despite these disappointments, however, Kidder was able to negotiate a final CIW field project in the Maya region of Mayapán.

MAYAPÁN: AN ARCHAEOLOGICAL SITE

Mayapán is one of the largest Mayan archaeological sites dating to the Late Postclassic period (ca. AD 1200–1542), the period immediately preceding the Spanish conquest of the area. The site is located about fifty kilometers southeast of Mérida, the capital of the southern Mexican State of Yucatán, and includes a nine-kilometer-long defensive wall enclosing an area of approximately 4.2 square kilometers. Within this area, the Maya constructed more than 4,000 buildings, most of which are residential. The site was densely populated with an estimated population of 10,000 to 15,000 people.

The site appears to have been constructed and occupied during the 300 years before the arrival of the Spaniards. Mayapán figures prominently in the various Maya chronicles that were written shortly before the conquest. Together with Uxmal and Chichén Itzá, it was thought to have formed a confederacy that exercised control over most of the Yucatán peninsula following the period of Mexican invasion. This assessment is no longer tenable as Uxmal is known to have been abandoned about 300 years before Mayapán was founded, and Chichén Itzá was reduced to the status of a minor center during the time Mayapán flourished. Bishop Diego de Landa, in *Relacion de las Cosas de Yucatán*, gives a lengthy description of a Maya capital and describes it as concentrically having temples and plazas in the center, the houses of lords and priests around this center, then the houses of the most important people, and finally the houses of the lowest classes.

Because the residential architecture corresponds to Bishop Diego de Landa's sixteenth-century description of Maya houses, the identification of the residential structures is comparatively definite and precise. According to historical accounts, Mayapán was abandoned about a century before the conquest of Yucatán, in about 1441 after conflict between competing ruling lineages.

Modern exploration of the ruins of Mayapán began with John Lloyd Stephens and Frederick Catherwood. They spent a day at the ruins and provided clear descriptions and illustrations of the two principal temples in the ceremonial center, the "Castillo" (Str. Q-162) and the "Caracol" (Str. Q-152). Stephens's observations were astute and he rightly assessed Mayapán as the ruin of a Maya city, in spite of the obvious differences between it and the other cities with which he was more familiar, like Copán and Uxmal. Moreover, he recognized that Mayapán was the same city described by the Spanish chroniclers as having been abandoned shortly before the Conquest. This fact was an important link in his argument that the Maya ruins "were not the works of people who have passed away, and whose history is lost, but of the same races that inhabited the country at the time of the Spanish conquest, or of some not very distant progenitors" (Stephens 1843, 2:307). This observation, so simple, clear, and obvious to this Emersonian New Yorker, was dismissed by his continental successors, not to mention most North Americans and even the Yucatecan intelligentsia.

Approximately two decades later, the French abbé Charles Etienne Brasseur de Bourbourg visited the site and provided a few additional details. He attempted to correlate some of his observations with Landa's description of the site. In general, however, "all of Brasseur's work is a weird pot-pourri of sound sense, great learning, absurd theories, groundless fantasies, and proof that is no proof, the whole in a spirit as remote as possible from the scientific" (Bernal 1980:108). Brasseur de Bourbourg was followed by the colorful Augustus Le Plongeon, in 1881, whose theories were even more removed from reality than were Brasseur's. It has also been reported that Teobert Maler drew Stela 1, but there is no published mention of a trip by him to the site.

EARLY CARNEGIE WORK AT MAYAPÁN

In the earliest decades of the twentieth century, no substantive work was done at Mayapán. It was not until the 1930s that more modern and scientific archaeologists took a look at the site. Not surprisingly, most of those archaeologists were affiliated with the Carnegie Institution of Washington and

its hydra-like program of Maya research. Lawrence Roys visited the site in 1936 (Pollock 1962:3) and wrote an article that attempted to trace the evolution of Maya architecture (Roys 1941). T. A. Willard visited the site in these years as well and provided an entertaining account of his trip (1941:221–233).

The first serious and detailed work at Mayapán was a survey undertaken by Ralph T. Patton, partly at his own expense but under the auspices of the Carnegie Institution. The survey was conducted because “the archaeological importance of Mayapán . . . appeared to be far less than its political preeminence in the thirteenth, fourteenth, and fifteenth centuries . . . would have demanded” (Morley 1938c:141).

Patton’s survey followed the Great Wall in its circuit around the site and also included the ceremonial center. He traced the circuit of the Great Wall and briefly described its construction. He showed that the masonry was dry-laid of large irregular blocks. It measured about nine kilometers long, three to four meters in thickness, and about two meters in height on the exterior. The parapet along the outer edge, the interior stairways, and nine of the portals were identified. The survey of ceremonial center revealed the presence of colonnades and four round structures, both rare forms of architecture in the Maya canon. The survey also located a number of stelae with short-count dates that Morley interpreted (Morley 1938c:142). It is apparent from other evidence, described below, that Patton located and mapped the main sacbe at the site and the large residential groups associated with it. Morley concluded that “although Mayapán reached a position of first importance only at the close of Maya history when architectural decadence was well under way, its size satisfactorily agrees with the political preeminence ascribed to it by both the native and the Spanish chroniclers” (1938c:142). Although Pollock later avowed that Patton’s map was of great help to Morris Jones in making the final site map (Pollock 1962:3) and Brainerd used part of his map of the ceremonial center as an illustration (Brainerd 1958:347), Patton’s work was never published.

Not long thereafter, in 1942, George Brainerd undertook the first intensive excavations at Mayapán, again under the auspices of the Carnegie (Brainerd 1942, 1948:21–23). Thirteen trenches were excavated, yielding a collection of more than 32,000 sherds. Brainerd was able to identify limited stratigraphic change in pottery types, notably the succession from Coarse Slateware (now Peto Cream ware) to Coarse Redware (now Mayapán Red ware), and the increasing frequencies of effigy censer fragments through time. In these observations, he anticipated

the findings of Robert Smith (1971) and established the main features of the Mayapán ceramic sequence. Brainerd’s analysis and conclusions were not published, regrettably, until the later and much more detailed investigations of the Carnegie Institution at Mayapán were almost complete.

Toward the end of Brainerd’s work at the site, E. Wyllys Andrews IV arrived and spent a month studying the architecture. He cleared, partially or completely, eight buildings, in addition to performing a number of other small excavations (Andrews 1942:261). He noted the reuse of Puuc-style stones in the Mayapán-period architecture but observed no standing Puuc architecture. He recognized the Temple of Kukulcan as a slightly reduced copy of the Castillo of Chichén Itzá and noted the resemblance of the largest of the round temples at Mayapán to the Caracol at Chichén Itzá. He described the Mayapán masonry in some detail, including the salient differences between it and the masonry at Chichén Itzá (1942:262). He also commented on the remarkable similarity between the Mayapán architectural style and masonry and that of the east coast of Yucatán. Based on his excavations at a number of sites in northern Yucatán, Mayapán included, he was able to sketch an outline of architectural evolution in Yucatán that stands to this day: Early Classic and early Late Classic block masonry was succeeded by Puuc masonry, followed by Mayapán-style masonry (1942:262–263).

CARNEGIE INSTITUTION WORK AT MAYAPÁN

By 1950 the work of CIW in Guatemala and the Petén lowlands was closed down, and the Late Postclassic period site of Mayapán was selected for extensive historical and archaeological investigation under the direction of Pollock. This research was to examine the final expression of pre-Hispanic Maya culture.

A meeting of the permanent Carnegie archaeologists was convened in Cambridge, Massachusetts, in July 1950 to discuss the upcoming field season. It was determined that the office, laboratory, and storage facilities were to be located in Merida and the field quarters in Telchaquillo, a small village a few kilometers distant from Mayapán. A five-year contract was executed at the end of October between the Carnegie Institution of Washington and the Secretariat of Public Education of the Government of Mexico through the Instituto Nacional de Antropología e Historia.

The operational goals and objectives of the research were summarized succinctly by H.E.D. Pollock (1958:446):

The program was designed to be compact and to reach the stage of drawing conclusions in a predictable number of years. It was, of course, based primarily on archaeology but with considerable reliance on the results of previously performed historical research. The locus of the research was the Yucatán peninsula, and the period under consideration was the approximately five centuries preceding the Spanish conquest. The focal point of field operations was the last important center of aboriginal Maya civilization, the ruins of Mayapán. Subsidiary operations were archaeological surveys and exploration in outlying areas thought to be important in the period under study, and an examination of certain known centers of Maya rule after the fall of Mayapán and during the final hundred years before the Spanish completed the conquest of Yucatán. The essence of the program, aside from the more usual archaeological objectives, was an experiment in linking the results of archaeological research with the knowledge derived from aboriginal and early Spanish written records in an effort to discover how much of the intellectual, or at least nonmaterial, content of a bygone civilization could be recaptured.

Extensive and detailed investigations were conducted at the site by a large team of experienced archaeologists over a period of five years (1951–1955) under the auspices of the Carnegie Institution of Washington. The staff of the project included many prominent Mayanists of the day, such as Edwin Shook, Tatiana Proskouriakoff, Robert Smith, A. L. Smith, J. Eric S. Thompson, H.E.D. Pollock, and Karl Ruppert, not to mention a group of graduate students and others who directed the daily work and wrote the field reports.

Anticipating modern trends in graduate student training, Mayapán included the first training program in the Maya region to actively employ groups of graduate students from various universities. Many of these students went on to productive careers as archaeologists and anthropologists. These included Robert McC. Adams and Howard Winters from the University of Chicago; William R. Bullard, David de Harport, Edward I. Fry, William N. Irving, William T. Sanders, Philip E. Smith, Donald E. Thompson, and Raymond H. Thompson from Harvard University; Ann Chowning from the University of Pennsylvania; Joseph A. Hester from the University of California, Los Angeles; and Charles R. Temple from Yale University.

This final CIW archaeological project was the first attempt at an extensive field investigation and typological and functional analysis of domestic structures, the first attempt to excavate a sample of the entire range of structural types at a single

Maya site, and the first systematic attempt to view a single Maya site within a regional framework. In addition, functional analyses were conducted on the larger civic and religious structures, and there was extensive use of the direct historical approach made possible by ethnohistorian Ralph L. Roys's historical research.

As early as the 1930s department director Alfred V. Kidder was concerned about the inability of fieldworkers to publish the results of their investigations in a timely manner. This problem was certainly not unique to the CIW program and continues to be a persistent problem today for a variety of reasons, such as the difficulty in raising funds for publication, the lack of time available to the average archaeologist for writing, and the casual attitude toward the "issuance of reports as an essential and immediate sequel" (Wauchope 1965:159). As possible solutions Kidder advocated shorter field seasons, the use of fewer workers, the preparation of annual publications, and the completion of up-to-date finished manuscripts before the start of a new field season or project. In 1940 a new publication series, *Notes on Middle American Archaeology and Ethnology*, began under the editorship of J. Eric S. Thompson. This series was a minor, albeit highly valuable, device for making available important information not likely to appear elsewhere. The papers included were brief notes on specific specimens or topics, and when the series ended in 1957, 131 short, but useful, papers had been published.

To ensure the rapid dissemination of the Mayapán Project's results two series of papers described the work being undertaken and reported the preliminary findings. These were volumes 50 through 57 of the *Year Books* and numbers 1 through 41 of the *Current Reports*. A total of forty-one *Current Reports* were published by the Carnegie Institution of Washington from 1952 to 1957. These publications were intended to be part of the reporting of the results of a program of archaeological and historical researches concerned with Yucatán and adjacent areas begun in 1949 and completed in 1956 (Table 1). Research reported in the *Current Reports* (CR) series included compilation of a site plan for Mayapán (CR no. 1), excavation of the wall enclosing the site (CR no. 2), excavation of specific structural types within the site core including temples (CR nos. 8, 14, 16, 20, 27, 30, 32, 34), excavation of ceremonial buildings (CR nos. 9, 21, 28), and excavation of residential and administrative buildings (CR nos. 19, 22, 25, 29, 31, 33). Beyond the site core, investigations were made of house mounds and domestic buildings (CR nos. 4, 10, 36, 39), boundary walls between these units (CR nos. 3, 13), and more peripheral sites (CR nos. 6,

7, 18, 23, 24). Other investigations reported include sacbes or "roads" (CR nos. 15, 37), cenotes (CR nos. 5, 11, 12), caves (CR no. 35), pottery (CR nos. 26, 40), and human (CR no. 38) and animal (CR no. 41) skeletal remains.

The *Current Reports* series was intended as a means of rapid but preliminary publication of field results (Coe 1956). A synthesis of the project's accomplishments was later published by Pollock, Roys, Proskouriakoff, and Smith (1962). A formal type-variety analysis of the Mayapán ceramics was issued in 1971 by Robert E. Smith in his monumental *The Pottery of Mayapán: Including Studies of Ceramic Material from Uxmal, Kabah, and Chichén Itzá*. By this time the Department of Archaeology at the Carnegie Institution of Washington had ceased to exist and Smith's study was published by the Peabody Museum of Archaeology and Ethnology at Harvard University. The original field notes are available at the Peabody Museum.

The formal closing of the department's offices and laboratory in Merida took place on January 1, 1958. In March and April field equipment was moved to Merida and eventually most field and office equipment was presented to Instituto Nacional de Antropología e Historia. The property of the field house in Telchaquillo was returned to its owners. Remaining scientific equipment, office equipment, and all scientific records were given to the Peabody Museum. Additional gifts of scientific interest were made to the University Museum of the University of Pennsylvania, the Middle American Research Institute at Tulane University, and to the R. S. Peabody Foundation for Archaeology in Andover, Massachusetts.

The permanent staff of the Department of Archaeology continued active careers as scholars and researchers. Harry E.D. Pollock (1901–1982), the department's director, joined the Peabody Museum as Curator of Maya Archaeology until 1968 when he retired with the title Honorary Curator. Tatiana Proskouriakoff (1909–1985) was appointed Research Fellow in Maya Art at the Peabody Museum and maintained a productive career as a scholar. Karl Ruppert (1895–1960) resigned from the Carnegie Institution in October 1956 after thirty-two years of service and retired to Santa Fe, New Mexico. Edwin M. Shook (1911–2000) accepted a position with the University of Pennsylvania in 1955 as director of the Tikal Project, at that time the largest archaeological project in the New World. He later continued his archaeological work on the Pacific Coast and in the highlands of Guatemala. A. Ledyard Smith (1901–1985) joined the staff of the Peabody Museum in 1958 and participated in excavations at

Altar de Sacrificios and Seibal in the Maya lowlands. His brother, Robert E. Smith (1899–1983), served as Research Associate of Middle American Ceramics at the Peabody Museum from 1965 to 1968 and then as an honorary research associate until his death in 1983. Gustav Strömsvik (1901–) retired to Norway after thirty-one years in the department. J.E.S. Thompson (1898–1975) was elected a member of the Faculty Board of Archaeology and Anthropology, Cambridge University, and was later knighted by Queen Elizabeth II in 1975.

POST-CARNEGIE INSTITUTION WORK AT MAYAPÁN

Clifford T. Brown, now a professor at Florida Atlantic University, conducted excavations in the residential zone of Mayapán starting in the early 1990s. These were the first excavations at the site in more than forty years. Brown discovered patterns of artifact style and function at the site, finding that the types of artifacts differed among households and groups of households in different parts of the site.

Carlos Peraza Lope, an archaeologist affiliated with the Yucatán office of the Instituto Nacional de Antropología e Historia, has been excavating and consolidating the major buildings in the ceremonial center since 1996. He has uncovered remarkable murals on several buildings. He also excavated a scatter of human bones that may date to the destruction of the site, a deposit originally found by Robert Adams (CR no. 9).

Almost fifty years after the Carnegie Institution of Washington investigations at Mayapán, the site was again the focus of a major archaeological study. The State University of New York at Albany's NSF-Supported Economic Foundations of Mayapán Project, directed by Carlos Peraza Lope, Marilyn Masson, and Timothy Hare, had as its primary goal the reconstruction of the production and consumption patterns of the various social sectors of the site. From 2001 to 2004 the project completed a surface survey of thirty-six milpas (encompassing 52.99 hectares) across the site area, representing 131 systematic surface collections from domestic refuse deposits. In addition, 189 test pits, 63 of which were near structures outside the city wall, were excavated. This team also completely excavated three domestic structures outside the monumental zone. Results of the field project are being formulated and a project bibliography is available at <http://www.albany.edu/ims/mp-bib.html>. Fieldwork has resumed under NSF support, and in 2008 the Economic Foundations project concentrated on the outlying ceremonial group of Itzmal Ch'en by the far east gate, excavat-

ing a large colonnaded hall, a mass grave, and a small house next to the group's cenote. The project also surveyed eight 1 km by 250 m transects extending in four cardinal directions outside the city wall, locating 347 previously unknown structures linked to Mayapán, its nearby contemporary settlements, and earlier sites. This important work, the subject of Bradley Russell's completed 2008 University of Albany dissertation, expands the known geographic extent of the Mayapán settlement zone to a distance of around 500 meters in all directions, with interesting variation in settlement density.

PRESENT VOLUME

In 2006 the University Press of Colorado published *The Carnegie Maya: The Carnegie Institution of Washington Maya Research Program, 1913–1957*. This volume made available to scholars once again the extensive data published in the CIW *Year Book* series. The present volume continues this project by republishing the CIW *Current Reports* series. The *Current Reports* are published as they appeared originally with a few exceptions. Obvious typographical errors have been corrected, and some place-names have been modernized. The content has not been changed.

Table 1. Contents of *CIW Current Reports*, vol. 1 (nos. 1–14), and vol. 2 (nos. 15–41), 1952–1957.

THE CARNEGIE MAYA II

December 1952

PREFACE

H.E.D. POLLOCK, EDITOR

The purpose of the present series is to make available as promptly as possible the results of work in progress. The advantages of prompt reporting seem almost too obvious to need comment. A fact sometimes forgotten, however, is that, aside from the information provided to others than our own staff, the task of ordering material for publication, no matter how simple or preliminary in nature, will often point to gaps in our knowledge and may lead to promising avenues of future endeavor. It is hoped, then, that these reports will serve the dual purpose of keeping archaeologists informed of our work, and of producing better and more profitable research on our part.

As in the case of any new series of publications, we are making something of an experiment. It is natural to assume that most of the reports will deal with field work, although there is no reason why occasional statements on the progress of library or documentary research should not appear. If pub-

lication is to keep current, each author must have his manuscript in the hands of the editor before returning to the field for a succeeding season. This means that presentation must be brief and rather strictly factual. As we shall usually be dealing with fragmentary bodies of material, a minimum of speculation is probably just as well, quite aside from the exigencies of a rigid time schedule. Just how complete any statement is will depend on the nature and stage of the project and on the amount of time available to the author from other duties. Indeed, some work will not be subject to annual reporting, but will have to await a certain stage of progress before any worthwhile information can be presented. It follows that individual reports may vary considerably in length and in completeness. Our aim will be one of practicability rather than of uniformity.

H.E.D. POLLOCK, EDITOR

CURRENT REPORTS
Carnegie Institution of Washington
Department of Archaeology

No. 1

December 1952 [First issued December 4, 1951]

MAP OF THE RUINS OF MAYAPÁN, YUCATÁN, MEXICO

MORRIS R. JONES

Carnegie Institution of Washington is deeply indebted to the United States Geological Survey for its fine co-operation in the work described below. Not only were the services of Mr. Jones made available for a considerable period of time in two successive seasons, but all necessary surveying equipment was provided. We should like most sincerely to thank Dr. W. E. Wrather, Director, and Col. Gerald FitzGerald, Chief Topographic Engineer, for their advice and assistance. Particular thanks go to Mr. J. O. Kilmartin, who acted in a liaison capacity between this Department and the Geological Survey in the original planning of the project and who later assisted in arranging for reproduction of the map.

The map of Mayapán discloses a pattern of remains quite distinct from that of any other Maya center so far mapped. Not only is the concentration of structures greater than is known for any comparable area, but the great majority appears to have

been dwellings. Because of these apparent differences, it seems advisable to sound a note of caution in making comparisons with other maps. The survey of Mayapán made a particular effort to include all building remains, no matter how small or insignificant. This has been done at no other Maya site, the more imposing ceremonial and civic structures, courts, and plazas having received the lion's share of attention. Although it is entirely possible, indeed probable, that comparable mapping operations at other ruins would not reveal any such concentration of dwellings as that which occurs at Mayapán, there is nevertheless the chance that remains of this sort would be found in considerable numbers and that the appearance of other maps would thus be altered. Only additional surveys will resolve this uncertainty.

H.E.D. POLLOCK, DIRECTOR,
DEPARTMENT OF ARCHAEOLOGY

The field work that resulted in the present map covered the periods from November 1949 to June 1950 and from November 1950 to February 1951. Drafting, lettering, and general preparation of copy for reproduction were completed during the summer and autumn of 1951. It was not possible for me to supervise or check the latter phase of the work. I should like to thank Mr. E. M. Shook and Mr. Gustav Strömsvik for their valuable assistance in establishing facilities for operation at the beginning of the project and for their advice in respect to procedures. I should also like to thank Mr. R. L. Roys for his help in the spelling of local Maya names, mainly those dealing with cenotes. The whole-hearted co-operation extended to me by Mr. H.E.D. Pollock was a major contribution to the completion of the project.

Telchaquillo, a small village 2 km north of Mayapán, was selected as a base of operations. The village is accessible from Merida by road, and proved to be a good location, mainly because of proximity to the ruins and the fact that the native labor supply in the village was both adequate and of good quality, the natives being interested in, and sympathetic with, the project as work progressed.

Reconnaissance and survey at Mayapán during 1938 by Mr. R. T. Patton (*CIW Year Book* 37:141-142) proved valuable in planning operations. Several facts were known about the site. The ancient city is surrounded by a wall, roughly oval, extending approximately 3,200 m east-west and 2,000 m north-south, the area outlined being 4.2 sq km. Ancient gateways are to be found at intervals along the wall. A large pyramid, many closely spaced colonnades, small pyramids, and three round towers form a main group a little west of the center of the walled area. Another rather small ceremonial center is just inside the eastern limit of the area.

The wall presented a distinct advantage in the making of the map because it forms a definite boundary, and during the course of the work exploration and mapping were limited to about 75 m outside the wall. Ruins were found within this outer fringe, and it is known that more are beyond it, but they are sparse and hardly worth the effort of mapping when so much lies within the primary area.

A scale of 1:2,500 had previously been decided on; the contour interval selected was 1 m. As there is no vertical control in the immediate area, an elevation of 25 m above sea level was assumed for point 0, so that all elevations and contours are based on this datum. At the end of the second season, in order to determine the error between the assumed datum and the true elevation, a line of levels was run from a known point at Hacienda Xcanchakan to the ruin

area. Elevations as shown on the Mayapán map were found to be about 8 m higher than their true vertical position. This error is of little consequence since the map is an isolated unit and all elevations on it are relative to one another.

Actual work was begun with the selection of a point of origin as close to the center of the city as could be determined from information available. This point, a triangle cut in bedrock, is located along the trail which connects Rancho San Joaquin with the main road running south out of Telchaquillo. It is 31 m northeast along the trail from the gateway into the ranch. In beginning the survey, point 0 was occupied with transit, and Polaris observations were taken at night in order to determine true north. As an azimuth mark, a cross was cut in the top of the southernmost pillar of the gateway into Rancho San Joaquin. The dense growth which covers the area, the low relief, and the absence of any high cultural features in the vicinity prevented picking a more distant mark. The south azimuth from point 0 to the mark was computed to be 28 degrees 54'24", and the approximate magnetic declination for the area is 6 degrees 30' east.

With the true cardinal directions determined, a plane-grid system was laid out over the area, the net, when completed, giving squares 500 m on a side with 100 m stations established along all lines. Each 500 m station was marked by a triangle chiseled in bedrock where possible or by a large hub where the point fell on soil. Hundred-meter stations were marked with hubs surrounded by piles of stone.

All lines had to be cut, and four men were kept ahead of the instrument party, clearing a path through the dense growth. Native workmen were trained to plumb-chain and to set stations exactly on line, work which they learned quickly and performed accurately. Grid lines were carried as far as the wall, where they were discontinued after explorations just beyond. While this work was being done, two men were employed cleaning brush from the wall to provide easier passage when the time came to do plane-table mapping along it. Establishment of the plane grid network, which includes about 20 km of line, was completed in seven weeks, the density of the bush slowing the rate of progress.

A system of numbering stations was established, and the squares formed by the projection lines were given letters. It was thought that these 500 m squares would provide convenient units for separate archaeological investigation should such prove desirable, and an attempt was made to locate the grid lines so as to include the Main Group within one square. The cutting of these lines afforded a clue to the density

of remains within the wall, and the first part of the survey showed that there are many more ruins at Mayapán than had hitherto been supposed.

Plane-table topography and culture were mapped by working first along already cleared projection lines. An area of approximately 50 m on either side of the line was included. After a square had been surrounded, the interior was mapped by cutting four lines southward from the four 100 m stations along the north edge of the square. By covering the area 50 m on either side of each interior line, the square was completely explored. Each square was treated similarly.

At the close of the 1949–1950 season a transit station was established atop the main pyramid in order to triangulate on three known positions which are part of a third-order closed triangulation net of the Mexican Government. The geodetic co-ordinates of the main pyramid were determined by this method to be latitude 20 degrees 37'47.88" north, longitude 89 degrees 27' 41.40" west.

The density of remains found within the wall is high. A rough estimate would set the number at 3,500 individual ruins which still can be detected, plus many terraces, all within an area of about 4.2 sq km. Many more, of course, have been erased by the constant stone-robbing that has gone on since the beginning of the Spanish occupation. Rancho San Joaquin, within the walled area, and Hacienda Xcanchakan, 4 km to the west, were constructed wholly or partially of stone from the ruins.

Only a small percentage of the remains appear to have been ceremonial structures or the like. Most of the ruins are small, averaging 10 by 5 m, and have a typical floor plan. It seems logical to assume that these small structures were dwellings. More often than not, two or three are so situated as to form an obvious unit, the remains being close together and on the same terrace. Metates occur frequently, and in many cases an altar is a definite part of the assemblage. It was noted that some of these units are made up of ruins slightly larger, better terraced, and in choicer topographical locations than the average. In

a few cases stone columns supplement what seems to have been the standard floor plan.

In summary, the remains found at Mayapán are numerous but the architecture appears to be far inferior to that of the other great cities of northern Yucatán. As has been mentioned, the ruins are in an extreme state of disrepair.

ROLLA, MISSOURI

EDITOR'S NOTE

The preliminary edition of the accompanying map of the ruins of Mayapán carries no numbering or other designation of the numerous buildings, platforms, and terraces shown there. It was thought that the numbering of structures or any labeling of ancient cultural remains had better proceed with the archaeological survey that has followed the making of the base map. In this connection it is assumed that at some future date a new edition of the map will be published, showing the number of each building and incorporating all changes and additional features developed by excavation and detailed surface study.

Numbering of structures is now in progress and reference to such designations will be found in succeeding *Reports*. As there is no key for locating the buildings on the published map, other than placing them in one of the lettered 500 m squares, some correlative system is needed. This is easily done by the simple use of co-ordinates measured north or south and east or west from the zero point of the map.

It will be noted that the distance in meters of each grid line from the zero point of the map is shown at the margin. The zero point is thus found to be the common corner of Squares K, L, Q, and R. Should we, for example, wish to pinpoint the center of Square K, it may be located as 250 N, 250 E, it being understood that distances are in meters from the zero point. The largest pyramid at the site, the so-called Castillo, is 225 S, 285 W. There is a sink hole at 45 N, 0 E, and another at 0 N, 1525 E. This system of co-ordinates will be used to locate any feature on the present edition of the map.

Revised edition December 1957

THE GREAT WALL OF MAYAPÁN

EDWIN M. SHOOK

INTRODUCTION

There are numerous references in the Maya chronicles and early Spanish colonial historical accounts of Yucatán relating to Mayapán. Few, however, give specific information concerning the Great Wall surrounding the ancient city. Nevertheless, statements in two sources are pertinent to this study, one in *Relación de "Quinacama" and Muxuppipp* and the other in Landa's *Relación de las Cosas de Yucatán*. The first, speaking of Mayapán, says (Tozzer 1941:24, no. 131): "This city conquered all these provinces, for it was very strongly built, walled in like those of our Spain, and within the walls there are reckoned to have been more than sixty thousand dwellings, not counting the environs." Landa writes (Tozzer 1941:23–26):

This Kukulcan established another city after arranging with the native lords of the country that he and they should live there and that all their affairs and business should be brought

there; and for this purpose they chose a very good situation, eight leagues further in the interior than Merida is now, and fifteen or sixteen leagues from the sea. They surrounded it with a very broad stone wall, laid dry, of about an eighth of a league leaving in it only two narrow gates. The wall was not very high and in the centre of this enclosure they built their temples, naming the largest, which is like that of Chichén Itzá, the name of Kukulcan, and they built another building of a round form, with four doors, entirely different from all the others in that land; as well as a great number of others round about joined together. In this enclosure they built houses for the lords only, dividing all the land among them, giving towns to each one, according to the antiquity of his lineage and his personal value. And Kukulcan gave a name to this city—not his own as the Ah Itzas had done in Chichén Itzá, which means the well of the Ah Itzas, but he called it Mayapán, which means 'the standard of the Maya,' because they

2.1. The Great Wall and Gates D, G, and H.

The whole rests on limestone bedrock. b. Section of the wall at 500 N, 1000 W. c. Section at 555 S, 980 E. d. Plan and sections of Gate D. e. Plan of Gate G. f. Plan of Gate H.

called the language of the country *Maya* and the Indians (say) *Ichpa* which means "within the enclosure."

Therefore, the existence of an enclosing wall at Mayapán has been known since colonial times. When Stephens (1843:1:131,143) briefly visited the site in 1841, he saw part of it and learned from the majordomo of the nearby Hacienda Xcanchakan that this strong wall, 4.8 km in extent, encompassed the ruins.

Modern investigations were first undertaken in 1938 by Ralph T. Patton (Morley 1938:5-6), who traversed and mapped the entire wall, established its

circumference to be 9.1 km, and identified nine entrances. As a result of Patton's survey, Tozzer (1941:24, no. 131) subsequently pointed out for the first time the probability that there were two walls at Mayapán, the larger one explored by Patton capable of having "within the walls . . . more than sixty thousand dwellings," and a smaller, inner walled enclosure to which Landa apparently refers, inside of which were "built the temples and . . . houses for the lords only."

The next field work producing significant information concerning the Great Wall was done by Morris Jones (1952) who mapped in detail the area within and for a short distance outside the enclosure. His map provided the basis for my further investigations during the 1952 field season.

This report is limited to the results of a complete reconnaissance of the Great Wall and the excavation of certain of its major and minor gateways. Preliminary search to date for traces of a small inner enclosure around the tightly grouped ceremonial precinct has been unsuccessful.

WALL

The Great Wall of Mayapán for the most part now appears as a white ribbon of stone rubble meandering more than 9 km through the low, dry, and exceedingly thorny Yucatán bush. This secondary growth, typical of the north-central and western portions of the peninsula of Yucatán, covers a seemingly soil-less and deceptively flat plain. The terrain actually is incredibly rough, as small, low hillocks of limestone bedrock follow one after another. What meager soil there is collects in the pot holes, crevices, and shallow depressions between these rocky knolls. The Great Wall undulates with the terrain, usually passing over the crests of the elevations but occasionally crossing the slope of a hill without regard to the natural contour of the ground. It encloses an area of 4.2 m² which extends approximately 3,200 m east-west and 2,000 m north-south. A glimpse at the Mayapán map (Jones 1952) will show that the wall around the western half of the site forms a fairly even arc about 1 km in radius from the central ceremonial group. Its generally circular shape is broken on the east side, however, by an extension which culminates in a sharp apex more than 2 km from the central ruins.

Even for such prodigious builders as the Maya the construction of this wall and its many gateways was an enormous expenditure of manpower. The builders first erected an outer primary wall rising on a slight batter to an average height of 1.5 m around the eastern half of the site, and in some places to 2 m around the western end. Against the inner face of the primary wall another lower one was built. The two together made a single wall very thick at the base and stepped at the top, the lower step on the inside forming a bench and the higher a parapet.

The stone for this great undertaking was quarried from nearby ledges and outcrops of bedrock. Huge blocks were broken and pried, hauled into place, and utilized without further shaping or dressing. Frequently some of the larger blocks were cut from the surface rock along the line of the wall and simply turned up on edge to form the lower facing (Fig. 2.4i). The wall facing of rough, uncut, and undressed limestone blocks retained a core fill of dry rubble, and the whole was built without mortar. Generally, smaller stones were employed both in the top facing and fill, with crushed rock composing the uppermost fill of the bench and parapet. This appeared to be the remains of a lime concrete surface, though nowhere along the entire wall was the latter preserved. Despite the lack of evidence, it is probable that originally the bench and parapet had been capped with a thin surface of lime mortar.

It may be stated here that the ruinous condition of the Great Wall and its portals appears to have been caused mainly by natural agencies. Minor damage, it is true, has occurred where the wall has been broken through for a modern trail or where the local people have removed stones to fence their cornfields. Nevertheless, the major damage has resulted from centuries of exposure to the elements, and from fast-growing roots of large trees which have penetrated the loose stones, gradually dislocated them, and caused the wall to crumble.

GATES

In this report each gateway is designated by the capital letter of the grid square in which it is located; e.g. Gate H is found within Square H on the Mayapán map. Their description begins with the principal north entrance, Gate D, and continues clockwise around the site. Prior to excavation it was decided to clear only one-half of each gate investigated, so as to keep undisturbed evidence for any future study.

Altogether, 12 ancient portals through the Great Wall were recognized during the 1952 season. These were classified on the basis of their plan as seven major and five minor gates. The latter are straight,

narrow passages; the former have a more elaborate ground plan. The entrances are wider in major than in minor gateways and lead into an amplified rectangular space suggesting a portico, but still set within the wall. The "portico" faces the interior of the enclosure and may have one or two stone columns or masonry piers. Besides the 12 gates identified, there may have been others, particularly minor ones. The original number is uncertain because of breaches made in the wall in postconquest times for roads and trails crossing the site. About 25 of these were noted, some wide enough to accommodate carts or trucks. Had there existed a minor gate where any of these modern breaches occur, all traces have been obliterated. Of the 12 known gates, one major and one minor had been blocked with masonry during the occupation of Mayapán. Presumably the others were in use simultaneously.

The study of gates was undertaken with specific problems in mind: Would we find pottery dumps in the vicinity of the gates indicating rites involving annual breaking of domestic and religious pottery and the deposition of idols? Would we obtain evidence of armories, guard houses, and of warfare? Special attention was therefore directed not only to the gateways and their immediate approaches but to the surrounding areas as well.

Intensive field work began at Gate D with the clearing away of the low scrubby bush and accumulated leaf mold from a circular area some 40 m. in diameter around the entranceway (Fig. 2.5a). Several of the larger trees were left standing where these did not interfere with the proposed work. Once the preliminary cleaning was accomplished, it became evident that Gate D had been built on a slightly elevated, natural hillock with the bedrock visible almost up to the entrance on each side. To be certain, however, that no offerings or ceremonial pottery dumps would be missed, we explored all the pot holes and crevices in the limestone and turned the thin mantle of topsoil from a distance of 20 m on both sides towards the portal (Fig. 2.1d). This was tedious and for the most part unproductive work, but it permitted certain conclusions; namely, that the surrounding limestone outcrop had been utilized as a stone quarry, and that no ceremonial dumps had accumulated in the immediate vicinity of the gate. Only one cache, a few broken artifacts, and a small amount of badly weathered pottery fragments were recovered from these excavations. The cache (Fig. 2.18c), a single miniature effigy vessel filled with ashes and covered with a tiny pottery lid, had been deposited as an offering in a shallow hole in the bedrock just north of and outside the portal (Fig. 2.1d).

Within the gateway fallen debris from the sides had covered and partially protected the thin, lime concrete floor of the passageway (Fig. 2.6c). Above this floor there was no indication of fallen roof material; hence, had Gate D been roofed, it could only have been with pole and thatch. After the clearing of the floor, a north-south trench following bedrock was dug through the gateway (Fig. 2.1d). The bedrock in many places was flush with the floor surface and only the slight depressions in the hill had been filled with loose stone and dirt.

The construction of this gate and all the others was the same as that used in the Great Wall, large, rough blocks laid without mortar (Fig. 2.5c–e). Even the interiors of the major as well as the minor gates were left unplastered except for the floors (Figs. 2.5b; 2.6c). The plan of Gate D is unusual in that the wall approaching either side thickens only slightly to join the north portion of the gateway which projects several meters beyond the exterior line of the Great Wall (Fig. 2.1d). A narrow passage was left in the center of this northern projection, which gave access to an enlarged rectangular space still set within the wall and herein termed a portico. This faced south toward the city, with a single masonry column placed on the central axis of the gateway. The column (Figs. 2.5b; 2.6b), like the wall and gates, was built of large rough block without mortar. Its purpose is uncertain but it may have served as a support for timbers had the gateway been roofed. The excavations below the column disclosed no cache or ceremonial offering.

The ruinous condition of Gate D was such that we were unable to determine if stairways led to the top of the wall from each side of the portico. Later, we noted stairways associated with several other gates.

Test cuts were made within a 100 m radius of Gate D wherever depressions showed an accumulation of earth. Despite the intensity of the search, no evidence (except the single cache vessel previously mentioned) indicating ceremonial deposition of pottery, battles, guard houses, or armories was recovered.

Following the investigation of Gate D, all trenches and pits were filled and stones replaced against the walls we had uncovered to prevent any future deterioration from our excavations.

East of Gate D no other ancient gateway was encountered until we reached the extreme northeast corner of the city, where the Great Wall sharply turns and continues in a southwest direction. In this distance of over 1.5 km two modern breaches occur where *milpa* trails crossed the wall. At the northeast corner the major Gate G was studied briefly but not excavated (Fig. 2.1e). Here the wall thickens from its

average of 2.5 m to 4 m, this extra width accommodating the passage and the portico. The entry, 2 m wide, in the outer half of the wall, leads into the portico which differs from Gate D only in that it probably has two masonry columns instead of one. Only the east column stands above the debris, but its off-center position suggests that another may be found buried just west of it. A broad stairway projects from the interior face of the wall, west of the portico, and leads to its summit.

As previously mentioned, the direction of the Great Wall at Gate G changes abruptly with almost a right angle (Fig. 2.1e) and meanders in a southwesterly course to another major entrance, Gate H, opposite an important group of ceremonial structures at Cenote Itzmal Ch'en. The wall widens rapidly as it approaches Gate H and, like G, the entrance and portico are built within the wall (Fig. 2.1f). The portico is not balanced in relation to the central axis of the passage, and no columns remain in place. A very large stone which may have been a column now lies above floor level where the outer passage enters the portico. No excavation was undertaken here because the exposed bedrock gave little hope of recovering additional information.

Continuing in the same southwesterly direction from Gate H, we found the next ingress, Gate U, a minor one. It consists of a simple passage, 1 m wide, resembling the excavated minor Gate AA, to be described later.

The next ancient opening, Gate T occurs at the extreme southeast edge of the site and is closely associated with two temples and Cenote X-Coton, located just inside the enclosure. This gate (Figs. 2.2a; 2.7; 2.8), a major one, was excavated in the same manner as Gate D. The southern half of the portal was thoroughly investigated. Also, owing to a fairly deep deposit of soil, a long stratigraphic trench was dug to bedrock for a considerable distance in both directions (Figs. 2.2a; 2.8d).

The plan of Gate T differed in minor details from D. The Great Wall approaching it spreads from the normal 2.5 m thickness to 6 m. A wide passage through the wall's outer portion gave access to the inner portico containing two large stone columns (Fig. 2.8a, b). In the interior corner of the portico was a low masonry bench, a feature not found at Gate D. The trench along the central axis of Gate T disclosed that the builders first leveled the general area, then added a layer of crushed rock to raise the floor of the gateway one step above the surrounding level (Figs. 2.2a; 2.8c). This dry crushed rock formed the base for an excellent lime concrete floor which remained unbroken, thus providing a sealed stratigraphic condition for the few pottery fragments found below

it. A later floor was constructed a few centimeters above and served to protect the earlier one. A small amount of pottery and artifacts recovered in the debris above the second floor included several fragments of a thin gold ornament and a pellet from a copper bell. As at Gate D, no evidence was brought to light indicating nonperishable roof material.

Just beyond Gate T the Great Wall turns west; only a short distance from the bend was discovered another major gateway, Blocked Gate T, which had been sealed with masonry during the occupation of Mayapán (Figs. 2.2b; 2.9). We excavated this gateway and found it to be the same as the other major ones except that the portico projected from the inner face of the wall instead of being set entirely within it or of being like Gate D. Also, no masonry or large stone columns were in the portico, but these may have been removed when the portal was blocked. That this entrance had been sealed while Mayapán still flourished was evident from the pottery fragments recovered on its floor beneath the secondary fill.

There is no obvious explanation why there should be two major gateways so close together at the southeast edge of the city. Although the nearby Cenote X-Coton and associated temples suggest the importance of the locality, one gateway seemingly would have sufficed, as apparently it did after the other was blocked. An attempt was made to determine if the sealed gate had been built prior to Gate T, but both appear to be contemporary with the walled construction.

2.2. Gate T, Blocked Gate T, and Gate EE.

a. Plan and east-west section of Gate T. b. Plan and section of Blocked Gate T, which was closed with masonry during the occupation of Mayapán. c. Plan of Gate EE.

From Cenote X-Coton the Great Wall continues west with some southward trend. A number of breaches occur along this stretch but in each case they are obviously for modern roads or *milpa* trails. As has been said, some of these breaches may have destroyed ancient minor passages. The first old one we were able to identify after Blocked Gate T was a

minor gate, almost 1 km. away at 890 S, 530 E. It does not show on the published map of Mayapán, and discovery of Blocked Gate X was accidental as it, too, had been sealed with masonry in ancient times. The stones used to close the 1.5 m wide passage had the same rough appearance as those in the wall, and the entrance was recognized only by the vertical lines of the exterior corners. No excavation was done on this previously unknown minor gate.

Farther southwest and just within Square EE at 1100 S, 10 W, is another minor gate. It is a straight, narrow passage, 1.3 m wide, now partially choked with debris fallen from each side. Minor Gate EE shows no unusual features and no excavations were attempted.

Also in this square, near its western edge, is the principal south gate in the Mayapán wall. This major entrance, Gate EE, still serves as a passage for a modern trail from Telchaquillo to the town of Chapab. The work at Gate EE consisted of clearing away the undergrowth in order to obtain photographs and a ground plan (Figs. 2.2c; 2.10), and the excavation of two small platforms directly inside the enclosure. These platforms, square in plan and each about 40 cm high, had been built of a single facing course of rough stones and filled with dry rubble. They rested on bedrock and presumably were surfaced with plaster, although none remained. We removed the stone fill of both platforms, subsequently replacing it, to determine if offerings had been put inside them. The east platform yielded nothing but the west one contained fragments of a porous gray ware vessel (Fig. 2.18a) which may have been deposited as an offering.

There were two periods of construction on Gate EE. Originally the portal was similar to Gates G, H, and T, built within a considerably thickened section of the Great Wall with a passage through the outer half leading into a portico. In this case the portico, though clearly definable without excavation, had no masonry or stone column. Probably one had existed and was removed in postconquest times to clear the passage for the modern trail. Secondly, a wall had been added against the outer face of the Great Wall extending for some distance east and west from the entranceway (Fig. 2.2c). This addition, 1.1 m thick, apparently reached the same height as the primary wall. Without increasing the latter's original height the extra thickness would not have made the Great Wall more effective for defense, but it would have helped retain or buttress those parts that may have shown signs of crumbling. Another example of this buttressing was noted at 1125 S, 125 W, where a section 20 m long and 1 m, thick was laid against the outer facing.

From Gate EE the Great Wall curves in a low arc to another major gate in Square O. About half-way between, at 700 S, 935 W, is a minor passage, Gate AA, which was completely choked with fallen debris. On investigation, this gateway, the only minor one excavated, proved to be a straight, narrow passage through the wall with a lime plaster floor (Figs. 2.3a; 11). The floor continued beyond the entranceway and merged with the natural limestone outcrop. The wall, as elsewhere, had been built on bedrock with its surfaces on the exterior and in the passageway faced with rough blocks laid without mortar or plaster. This gate, as well as other minor ones, probably had not been roofed as no roof material was noted in the debris.

Gate O (Fig. 2.3d,e), the main western entrance to the city, was not only the best preserved but the largest and most elaborate in the Mayapán wall. We investigated this major portal more thoroughly than any of the others. An area roughly 50 m in radius was completely cleared of vegetation to permit study of the terrain and detailed excavations (Figs. 2.12, 2.13). Gate O was built on the north slope of a hillock rather than on the crest. The orientation of the entrance was such that as one entered the narrow outer passage he faced the temple of Kukulcan, the largest pyramid at the site, situated 1 km away in the heart of the city (Fig. 2.12b). The narrow entrance led to an inner portico with two columns, one of which was built of many irregular blocks, the other of a single large stone. The portico gave on a low terrace where a plain stela once stood on the center axis of the gateway (Fig. 2.13b). Beyond the terrace and slightly off the gate's axis was a square masonry platform, 50 cm high, supporting another unsculptured stela. These two monuments were examined carefully and, although severely burned by *milpa* fires, quite certainly bore no carving. Their surfaces originally may have been plastered and painted, but no evidence of this was found. We exposed the exterior of the square platform (Fig. 2.13a,d), then cut a north-south trench through it on the level of bedrock. There was no offering below the stela or in the fill of the platform. Also, no chronological difference could be observed between the few sherds recovered from the exterior and those from the interior.

A trench dug through Gate O following bedrock exposed in section the lime concrete floor which surfaced the terrace, the interior of the gateway, and the outside for some distance west where all trace of the floor was lost because of the destructive action of tree roots. It probably merged with the limestone outcrops about 10 m from the gateway (Fig. 2.3d). Within the portico low benches had been added later

2.3. Gates AA, B, and O.

a. Plan and section of minor Gate AA. b. Plan of minor Gate B. c. Gate O, Section y. d. Plan of Gate O and east-west section through the center of the portal. e. Gate O, Section x.

on each side of the passageway. These benches bore a finishing coat of plaster which smoothly joined the base of the portico walls but did not cover their rough block facing (Fig. 2.13f).

On the inside of the enclosure, north and south of the portal, were broad stairways leading to the top of the Great Wall (Figs. 2.3d,e; 2.13c). Such extensive stairways suggest a use other than the convenience of guards patrolling the gateway. Their purpose may have been to accommodate a large number of spectators observing pageants or ceremonies in the vicinity of the gate.

From Gate O the Great Wall continues northward for some distance and slowly turns east. About halfway between Gates O and D, at 540 N, 550 W, is a clearly defined minor passage, Gate B (Fig. 2.3b). It is wider than the normal minor entrances and here the wall thickens considerably approaching the ingress. Also, on one side of the passage there is a stairway leading from within the enclosure to

the top of the wall. Nevertheless, Gate B is a minor one because it lacks the interior portico and accompanying columns. From here to Gate D there are no further ancient passages through the wall.

MATERIAL CULTURE

A scant quantity of artifacts and potsherds was recovered from the intensive investigations of three major gateways, D, T, and O, and the lesser excavations at Gate EE, Blocked Gate T, and minor Gate AA. Especially difficult to explain was the absence of any artifacts, especially stone tools, in and around the quarries near the Great Wall and gates. Here one might expect to find whole or broken stone implements utilized in the quarrying operations. The few artifacts and weathered fragments of pottery we did recover were found mostly in the thin topsoil and were widely scattered inside and outside the portals. An inventory follows:

2.9. Blocked Gate T.

a. The blocked major gate at 500 S, 1220 E, from the interior portico, showing the east side of the passage through the outer wall. b. After removing part of the second masonry which sealed the passageway.

OBJECTS OF STONE

OBSIDIAN. All clear to slightly cloudy transparent black stone.

Flake blades. Total fragments 16; 9 from Gate D, 7 from Gate O. Blades 6.5–15 mm wide. Only complete one 52 mm long (Fig. 2.14a; Cat. no. 52-51).

Scraper thumbnail. One from Gate D (Fig. 2.14b; Cat. no. 52-521). A small obsidian flake secondarily chipped on one edge.

Chipped point. 1 from Gate D (Cat. no. 52-52), only a fragment of the stem recovered. Excellent workmanship.

Comment. All the obsidian objects appear to be the same quality stone, suggesting that the people of Mayapán obtained their material by trade from a single source in the Guatemalan or Mexican highlands.

FLINT OR FINE-GRAINED LIMESTONE. White, pink, or yellow to pale brown opaque stone.

Flake blades. 2: 1 from Gate D (Cat. no. 52-50), 1 from Gate O (Lot B-2; Fig. 2.15 right). Both incomplete, pressure-flaked from a flint core. Resultant blade short, wide, and with irregular edges.

Chipped points. 4: 3 from Gate D (Fig. 2.15, left and left center; Cat. nos. 52-23,-50), 1 from Gate O (Fig. 2.15, right center; Lot B-2). Workmanship mediocre.

Hammerstones (?). 3: 2 from Gate D (Fig. 2.16, right; Cat. nos. 52-49,-48), 1 from Gate AA (Fig. 2.16, left; Cat. no. 52-167).

Metate. 1 fragment (Fig. 2.17) re-used in the construction of the Great Wall at 55 S, 810 E. Prior to serving as a metate, this stone had primarily been

well cut, dressed, and used as wall facing in a building probably of Puuc-style architecture.

Comment. The artifacts of flint and limestone were derived most likely from stone obtained in the immediate environs of Mayapán. The workmanship is inferior.

OBJECTS OF METAL

GOLD. Six small fragments of a single ornament which lay on the upper floor of Gate T. The pieces are flat and extremely thin, approximately 0.1 mm in thickness. It is not gold leaf, as each piece is stiff and brittle. The six together cover an area about 1 cm square. All have traces of green enamel (?) on one side.

COPPER. One solid irregular pellet, 5 mm diameter, apparently from a copper bell. This was found with the fragments of gold.

Comment. Metal artifacts represent importations from an area outside the peninsula of Yucatán, possibly Honduras or Mexico.

OBJECTS OF POTTERY

During the excavations the pottery was kept in separate lots from locations inside and outside the gateways, within the portals, below floors, and in fill of platforms. Each lot was washed, analyzed, and recorded individually; then, if no statistical or chronological differences could be observed, all material from a single gateway was placed together and given one lot number. For example, all pottery from

2.13. Gate O.

a-c. Three views from the interior after the area had been thoroughly cleared but before excavation. a. In the immediate foreground are the remains of a square masonry platform on which stood a plain stela. Beyond and at the extreme right is the portal. b. A closer view of the portico with its two columns, 5-x, and the outer passage where a workman stands. [y] indicates a plain fallen monument, now resting on the low terrace seen in the immediate foreground. c. The men are standing on the broad stairway leading to the top of the wall north of the gateway. d. The masonry platform shown in a, looking northeast. e. The south half of the portico after excavation. f. The unplastered rough block masonry of the portico showing the lime concrete floor joining the base of the wall.

d

e

f

Gate D is marked B-1, from Gate O, B-2, Gate EE, B-3; whereas from Gate T there are two lots, B-4 from above the portico floor and outside the entranceway, and B-5, a small lot recovered below the unbroken

floor of the portico. These five ceramic lots total only 172 rim and 610 body sherds. Only a brief summary will be given in this report of the pottery from the Mayapán wall and gateways.

2.14. Obsidian Artifacts.

a. Flake blades. b. Small "thumbnail" scraper. Both drawings natural size.

Fifty percent of the rims and body sherds are from a single type bearing a red slip. This has been termed Mayapán Red Ware. Shapes include water jars, tripod bowls with straight flaring sides, and restricted-orifice vessels. The next most common pottery, contemporary with the Mayapán Red Ware, is a coarse, unslipped, light Gray Ware (Fig. 2.18a,c) of very poor quality. It is soft and may be crumbled easily in one's fingers. The use of such inferior pottery may have been restricted to ceremonial objects such as figurines, effigies, and containers for offerings. Gray Ware occurs most frequently in the form of a wide-mouth, low-neck jar (Fig. 2.18a), with light striations on the shoulder.

Another ceramic type, Puuc Slate Ware, which we believe to represent an occupation of the site predating the period when Mayapán became a walled political capital, was found in minor quantities everywhere except at Gate T (Lots B-4 and B-5). Here more than half of the total pottery excavated was slate ware. The high percentage of this ware at Gate T may be accounted for by the evidence of considerable architectural and ceremonial activ-

2.15. Obsidian Artifacts.

a. The two fragments on the right are flake blades, the others chipped points. The complete point from Gate D measures 12.5 cm long.

2.16. Hammerstones (2).

a. The stone on the left (Cat. no. 52-167) lay on the surface outside Gate AA. The other two (Cat. nos. 52-49, -48) came from Gate D. Height of stone at left, 9.5 cm.

2.17. Metate.

a. Fragment re-used in construction of the Great Wall.

ity around Cenote X-Coton prior to the Mayapán period. Despite the predominance of slate ware from Gate T, pottery from below the unbroken portico floor included the typical red and gray wares found at the other entrances.

DISCUSSION

The Great Wall of Mayapán encloses not only the temples and houses of the lords but most of the general residential area as well. The wall was constructed, as evidenced by the style of masonry and associated cultural material, during the major occupation of this site as a political capital. The investigations herein reported did not disclose conclusive evidence of warfare, of guard houses or armories, or of religious rites involving the ceremonial break-

ing of pottery and the deposition of idols around the entrances to the city.

Special attention was given to the terrain adjacent to the portals for remains of formal roads or sacbes from the exits, or avenues leading toward the heart of the city. None was identified, and it seems evident that only unimproved trails led to and from the city portals. Today, the Maya living in the region have no tradition concerning the wall or its gateways. The only instance of an ancient ingress now being utilized is Gate EE, through which passes a modern trail from Telchaquillo to the village of Chapab.

Why was the Great Wall built? The first thought and perhaps the simplest explanation would be for defense. There is good reason to believe from Landa's account and other historical sources that the last few centuries before the Spanish conquest were turbu-

2.18. Pottery from the Excavations.

a. Unslipped, coarse, light gray vessel (Lot B-3) from the fill of the west platform at Gate EE. Scale 1:4. b. Hollow, moldmade figurine head (Cat. no. 52-47) from Gate D. Maximum width, 5.2 cm. c. Cache vessel (Cat. no. 52-46) containing ashes found outside Gate D. This miniature turtle effigy and the small flat cover were crudely wrought of coarse, light gray pottery like the vessel in [a], and left unslipped. Maximum diameter, 8 cm.

lent ones for the inhabitants of Yucatán and that there existed a real need for defense of their towns and cities. The Mayapán wall may have been erected to fortify the seat of government. It had a slightly higher parapet along the outer edge and a lower inner bench, or walk, which would have favored the defenders. It must be restated, however, that the wall's height ranged only from 1.5 to a maximum of 2.5 m at a few exceptional points where it crossed low ground. The average throughout the entire length was about the height of a normal man. Ralph L. Roys suggested to me that the existing wall may have been a stone base for a stockade of wood poles set close together and lashed with vines. This interesting hypothesis could not be verified in the field.

There are several other possible interpretations. The wall may have been constructed to delimit the city boundaries for administrative purposes. The site of Mayapán was selected as the national seat of religious and civic authority for a large part of the Yucatán peninsula and presumably the area necessary for this capital had to be requisitioned from land belonging to some individual state or states. The wall, then, could have marked the extent of the district under jurisdiction of the national government. It also may have been a means of control of commerce, taxation, or the liberty of a large number of inhabitants such as servants, laborers, and artisans employed by the priesthood and ruling class of Mayapán.

RESIDENTIAL PROPERTY WALLS AT MAYAPÁN

WILLIAM R. BULLARD JR.

The initial surveys of Mayapán disclosed the existence of a great number of field-stone walls running everywhere among the ruins (Pollock 1951:226; Ruppert and Smith 1951:232). While some walls were clearly *milpa* fences or cattle enclosures of post-conquest construction, others seemed contemporary with the occupation of the site. Many of the latter appeared to surround house structures and it was consequently thought that they might delimit property boundaries. During the season of 1952, we followed out and plotted on the Mayapán map all the walls in certain representative portions of the city. It was hoped that such a study might reveal the function of the walls and cast light on land tenure, city organization, and similar features. While stone fences around the houses are a regular feature of modern Yucatecan villages, they have not previously been reported from a preconquest Maya site.

The walls were completely plotted in roughly 1 sq km of the city, comprising specifically Squares D

and K in the north-central part and Squares 2, AA, BB, DD, and EE in the southwest part (Jones 1952, map). In addition, other areas of Mayapán were reconnoitered in order to determine the value of additional work.

The entire site is covered by what seems a maze of stone walls, ranging in age from the occupation of the city to the present day. For many years Mayapán was the site of a Spanish cattle ranch, and stone corals and enclosures were built throughout the central part of the ruins. Moreover, probably ever since the conquest there have been *milpas* within Mayapán, as there are today. Finding plentiful stone at hand in the ruined buildings and walls, the Maya farmers often erect stone fences around their fields, not hesitating to repair and reuse older walls when convenient. Centuries of such destruction and rebuilding have confused to a large extent the old wall patterns. Relatively few ancient walls are complete and in many instances only short sections could be followed. Although even

3.1.

Plot of Walls in Southwest Section of Mayapán (see map with *Current Report 1*).

fragmentary walls could usually be related to house structures, the complete pattern of ancient walls over a large area was all too often obscured. In this respect, the walls plotted in the extreme southwestern part of the site proved most satisfactory since here disturbance had been relatively slight (Fig. 3.1).

Another perplexing problem was to distinguish ancient from postconquest walls. Technologically, there are few reliable criteria that can be applied to tell a postconquest wall from a rebuilt ancient wall, or an ancient wall from an old and much destroyed postconquest wall. Thus, although the majority could be identified without difficulty, many had to be marked as questionable.

The ancient walls themselves are essentially alignments of uncut stones, set on edge, either touching or placed a few centimeters apart (Fig. 3.3a,b). The average height of the standing stones is 50–70 cm, but some walls are composed of large slabs up to 1.5 m high. Walls in areas free of postconquest disturbance often have smaller stones and spalls lying near their base, suggesting that the spaces between

the slabs were chinked and filled so that the tops of the walls were level rather than jagged as they appear today. Occasionally chinking stones remain in place in a few walls. In no case, however, was sufficient debris found to warrant the belief that the walls rose substantially higher than the stones now standing. Many modern stone walls in Yucatán are similar in that they utilize large slabs set on end as a base, but today they must be built high enough to prevent cattle and horses from crossing, a problem the ancient Maya did not have to consider.

In nearly all instances the walls wholly or partly surround individual dwelling houses or individual house groups (Fig. 3.2). House groups, although there is considerable variation, generally consist of two or three dwelling-type structures in a quadrangular arrangement, often built on a single terrace. Only rarely is more than one such house group surrounded by the same wall. Although many walls are fragmentary, enough remains were found to indicate that almost every domestic house or group had a wall. In contrast, present evidence suggests that

3.2. Plans of Property Walls.

a,b. Simple enclosures (1200 S, 330 W; 940 S, 650 W). c. Enclosure on one side of house group (630 S, 440 W). d,e. City wall as one boundary of enclosure (1040 S, 620 W; 710 N, 360 E). f. Use of common walls by neighboring house groups (685 S, 700 W). g. Entrance over house terrace (600 S, 630 W). h,i. Entrance through house (700 S, 115 W; 770 S, 820 W). j,k. Entrance formed by overlapping ends of wall (980 S, 670 W; 940 S, 120 W). l. Spiral wall (800S, 690W).

3.3. Property Walls, Gateways, Lanes, Circle.

a. Typical wall (975 S, 535 W). b. Wall built of large slabs (1130 S, 315 W). c. Gateway (605S, 260 W). d. Gateway with lane leading to house platform (220 N, 265 E). e. Lane (730 S, 715 W). f. Stone circle (1000 S, 170 W)

temples and public buildings such as colonnades are not surrounded by walls.

The enclosures formed by the walls usually include only enough space for a small yard around the structures. Most enclosures are of fairly simple plan, tending to be roughly circular or rectangular with rounded corners. There are more complex examples, however, especially around some of the

larger houses (Fig. 3.2d). Unfortunately, few of these are at all complete.

The buildings may be surrounded completely or the walls may abut against a house or terrace corner so that the structures are only partly enclosed (Fig. 3.2a-c). Houses adjacent to the city wall used this as one boundary (Fig. 3.2d,e). It is not unlikely that the yards around some buildings were never completely

fenced and this may explain some of the many apparently incomplete walls that were found. In the more densely settled districts, where the houses are close together, the enclosures become more irregular and neighboring groups share common walls (Fig. 3.2f). The system of walls in such an area may become exceedingly complicated (Fig. 3.1).

In a few instances the walls join a structure in such manner as to suggest that the yard was reached by crossing the terrace or by passing through the house, as is common in modern Maya villages (Fig. 3.2g-i). In other instances the two ends of a wall overlap, forming an entrance passage between them (Fig. 3.2j,k). One example formed a spiral around the house (Fig. 3.2l).

A few gateways were identified. They consist of a gap about 1 m wide between two stones somewhat larger than the other wall stones and often set, like door jambs, at right angles to the course of the wall (Fig. 3.3c). From one gateway a short lane formed by two parallel walls led to the stairway of a house terrace (Fig. 3.3d). Probably most enclosures originally had gateways. Certainly the walls which completely encircle a house group, such as those illustrated in Figure 3.2a,b,e,f, must have had openings, but the collapse of wall stones or postconquest rebuilding has nearly always made it impossible to determine their location. Even so, it is surprising that more gateways were not encountered.

There seems little doubt that the walls mark property boundaries around the houses. Evidently each household or family group had its own fenced yard. This does not necessarily imply, however, that there was private ownership of land in the modern sense. Quite possibly property was held only by permission from higher authority. While many yards are sufficiently large and on suitable terrain for the raising of fruit trees and small gardens, others include only the tops of the rocky hillocks which were the preferred house sites but which seem unsuited for horticulture.

Present indications are that the properties surrounding the larger and more elaborate houses, where the wealthier and more important residents presumably lived, were not markedly larger than those of the more humble homes. Further work, however, will be necessary to solve this problem.

Nothing was found in the areas plotted resembling a formal arrangement of streets. The houses are distributed irregularly and passage through the city evidently was accomplished by winding through the gaps between neighboring walls. Sometimes, particularly where houses are close together, the parallel walls of adjacent enclosures form short, often winding lanes about 2 m in width (Fig. 3.3e). Figure 3.1

shows an area where the lane system is especially complex. As previously noted, postconquest disturbance is at a minimum in this part of the city.

While most lanes are passages between properties, a few seem to run independently of property walls. Unfortunately, most of the latter were found near the close of the season during reconnaissance of the eastern part of the site, and no detailed plotting was done. Additional work will be necessary to clarify their function and their position in the whole settlement pattern. One lane ran to a natural depression about 3 m in diameter, now mostly filled with soil. In another location, four lanes converged on a small cave with three or four steps leading into it, possibly a blocked cenote entrance. Two of the four lanes were part of a series of lanes which could be followed in an almost straight line for nearly 400 m through an area in which houses were rather sparse. The complete examination of this lane system would be a worthwhile study.

Another interesting feature is the small stone circles occasionally found near a house group. They average 2–5 m in diameter and are constructed in the same manner as the boundary walls (Fig. 3.3f). Some are almost perfectly circular; others are more oval. One was built against a high house terrace so that the terrace wall formed one side. Often there is no gap that could have served as an entrance. Some would make excellent pens for small animals, but identification of their purpose without further information can be only guesswork.

There are several cenotes in the squares examined. The ancient wall patterns around them are not always as clear as we should like, but the data indicate that cenotes were ordinarily in the areas between systems of boundary walls, and thus accessible to the general populace, as would be expected.

Additional work on the Mayapán walls will be necessary to pursue several problems. We need to know, for example, more about the long lanes found during exploration of the eastern part of Mayapán. Moreover, further work in areas where the ancient wall pattern is relatively complete can be expected to give fuller understanding of such questions as the correlation of size of property with size and elaborateness of the house groups.

The most important results of the present work, to summarize, are the following conclusions. Each and every household or family group seems to have had a fenced yard around its residence. Temples and public buildings, on the other hand, apparently were not fenced. There was no formal arrangement of dwellings or streets in the residential areas of Mayapán, although narrow, winding lanes afforded access to houses in crowded districts.

EXCAVATIONS IN HOUSE MOUNDS AT MAYAPÁN

KARL RUPPERT AND A. LEDYARD SMITH

The dwelling-type structures at Mayapán follow closely Landa's description of native houses in Yucatán in the sixteenth century. A large number of these structures are shown on the map of Mayapán (Jones 1952). Essentially they consist of a front and a back room but with considerable variation in detail of floor plan (see Ruppert and Smith 1951:231). Landa says, "... they build a wall in the middle dividing the house lengthwise, leaving several doors in the wall into the half which they call the back of the house ... and the other half ... has no doors, but is open the whole length of the house" (Tozzer 1941:85-86). Landa further writes of the commoners being buried in or behind their houses (Tozzer 1941:130). The presence of burials in the Mayapán structures, therefore, provides evidence to corroborate our identification of dwellings, as well as offering additional information on burial practices. It is also hoped that the grave furniture and other remains derived from excavation will throw

light upon the household economy of the aboriginal Maya.

During the 1951-1952 survey of dwelling-type structures likely places for excavation were noted. Such locations consisted of depressions in benches or any visible construction below bench level, such as exposed capstones or bared vaults or walls. Besides digging in places where definite subfloor constructions existed, we made exploratory pits in benches. These excavations revealed tombs, cists, and a refuse dump. Test pits were also made in the terraces supporting structures.

Our work clearly indicated that the tombs and cists were built at the time the structures were erected. In this paper a cist is considered as a stone-lined pit which may or may not have been built for burial purposes but in which there is no indication of human burial. A tomb is similar to a cist but contains evidence of human burial. Since such evidence was found in three instances, it is possible that all cists

were built in preparation for interment, presumably of the occupants of the house.

Material recovered from a single locality, such as a pit, tomb, cist, or stratified area, is designated by a lot number. Sherd material was turned over to R. E. Smith for examination (see R. Smith 1952, Table 1). It is significant that in all excavations pottery of the major, and supposedly latest, period of occupation of Mayapán was recovered. However, it is interesting to note that in one instance (Str. J-49a) the earlier, Puuc type of pottery predominated.

All material recovered from excavations is listed in the captions of the figures under the lot number to which it belongs. Two cow's teeth need some explanation. They were found in the midden under the east bench of Structure J-50a (Lot A-13). Here one of the capstones had fallen, leaving the pit unsealed, so the teeth may well be intrusive.

We wish to thank Drs. Robert T. Hatt, Josselyn Van Tyne, Robert W. Storer, Norman Hartweg, T. Edinger, and Miss Barbara Lawrence for identification of mammal, fish, and bird bones.

STRUCTURE J-131A

(50 N, 520 E)

STRUCTURE J-131A (Fig. 4.1) is located on the east side of a two-structure group. It shows the remains of two benches. The south bench is in better state of preservation than the north.

SOUTH BENCH. When first examined, capstones and some vaulting of what proved to be a tomb were exposed under the south end of the bench.

TOMB (Figs. 4.1, Lot A-1; 4.6a,b). Measures 1.25 by 2.00 m. Floor of well-packed lime mortar 1.30 m, below floor of J-131a. Walls rise 75 cm to offset of vault. Stepped vault rises 75 cm. Most of vault stones had fallen into tomb. Three capstones recovered, of which two were in position. At west end the wall rose vertically at least 1.10 m. The tomb was filled with debris to height of end walls. Plaster still remains on walls to height of vault offset. Masonry of medium-sized blocks. Vault stones not beveled. Bedrock lies 12 cm below floor.

Material found in the tomb is described under Figure 4.1, Lot A-1. The skeletal remains, mixed and scattered throughout the fill near the floor level, indicate the presence of two adults, one lying flexed on its left side facing south against the south wall, the other flexed lying on its right side facing the same wall. The remains of a third skeleton, an infant, were found under a large drum-shaped stone in center of the tomb (Fig. 4.1, Lot A-1,2).

NORTH BENCH. A sink in the south end of the bench suggested a tomb.

TOMB (Figs. 4.1, Lot A-2; 4.8b). Measures 1.15 by 1.60 m. Floor very uneven and 1.25 m below terrace floor on which Structure J-131a rests. Masonry much cruder than in tomb under south bench. Skeletal material concentrated near floor in north half of tomb. The two skulls in northeast corner, placed with top of head downward resting on the floor, suggest secondary burial.

PIT (Fig. 4.1, Lots A-3,-4). Pit beneath north bench to north of tomb showed fill of small stones with much lime mortar.

GROUP J-49

(300 N, 690 E)

STRUCTURE J-49A (Fig. 4.2a), a single-bench building, is located on the west side of a two-structure group. Walls of a cist were exposed when first examined.

CIST (Figs. 4.2a, Lot A-8; 4.7a). Measures 1.25 by 1.95 m. The floor of rough lime plaster 2 cm thick lies on bedrock 1.05 m below top of bench. Cist filled with loose earth and stone to within 45 cm of top of bench. No capstones recovered. Block-type masonry. No plaster on walls. A few sherds and some obsidian and flint chips recovered (Lot A-8).

PIT (Figs. 4.2a; 4.8e, Lot A-22). Measures 1.40 by 1.60 m, depth 1.40 m from top of bench to bedrock. Sherds and an obsidian core, 9.3 cm long, recovered.

PIT (Figs. 4.2a; 4.8c, Lots A-10; -12). Measures 1 by 1.50 m. A floor or plaster work-level encountered 60 cm below top of bench. Area above that level designated as Lot A-10. Pit extended 1.15 m below plaster line to bedrock (Lot A-12). All fill of stone and mortar tightly packed.

STRUCTURE J-49B (Fig. 4.2b). A two-bench structure with the west bench L-shaped.

EAST BENCH. In good state of preservation. No indication of cist before excavation was undertaken. Lot A-6 from bench above the stone-lined cist.

CIST (Figs. 4.2b, Lot A-7; 4.7b). Measures 1.10 by 1.95 m. and 82 cm deep. Masonry very rough but covered with heavy layer of lime plaster. Floor of smoothly troweled plaster. In south wall 55 cm above

4.1. Excavations in Structure J-131a, Plan and Section.

Lot A-1. Contents of tomb under south bench: 1. Shell ornament, 6.1 cm greatest diam., Cat. no. 52-61 (Fig. 4.8d). 2. Drum-shaped stone, 22 cm high, 40 cm diam., slightly hollowed out on under surface. 3. Pottery whistle seated monkey (?), 4.2 cm long, Cat. no. 52-60 (Fig. 4.8d). 4. Flint blade, 9.5 cm long, Cat. no. 52-62 (Fig. 4.8d). 5. Adult mandible. 6. Adult skull, some infant long bones nearby. 7. Adult leg bones. 8. Infant skull under 2. 9. Adult jaw bones and skull fragments. Miscellaneous objects: fragment of obsidian blade, 3.8 cm long, Cat. no. 52-63 (Fig. 4.8d); broken piece of obsidian; sherds; animal bones, opossum, gopher. Lot A-2. Contents of tomb under south end of north bench. 1. Hexagonal shell ornament, 3.7 cm greatest width, Cat. no. 52-67 (Fig. 4.8b). 2. Shell ornament perforated for suspension, 3.2 cm long, Cat. nos. 52-66 (Fig. 4.8b). 3. Pottery figurine of a man, 10.2 cm long, Cat. nos. 52-65 (Fig. 4.8b). 4. Pottery figurine of a woman, 8.6 cm long, Cat. nos. 52-64 (Fig. 4.8b). 5. Adult skull. 6. Adult skull. 7. Human leg bones. 8. Human leg bone and foot bones. Miscellaneous objects: two small pieces of charcoal and a deer antler, 9.9 cm long, Cat. no. 52-68 (Fig. 4.8b); filed human tooth, Cat. no. 52-226 (Fig. 4.8b). Lot A-3. Contents of top 30 cm of pit under north half of north bench: sherds. Lot A-4: Contents of bottom meter of pit under north half of North Bench: sherds. a. North bench. b. South bench. c. Low terrace wall on west side of Str. J-131a. d. South wall of main terrace supporting group. e. Line of stones at terrace level. f. Fill of small stones and lime mortar. g. Open fill. h. Coarse *sascab* fill.

floor and 38 cm from the southwest corner is a stone plug projecting 6 cm. In east wall of cist is a recess roughly 56 cm wide by 75 cm deep. The opening has a width of 40 cm. Floor of recess 25 cm above floor of cist. Resting on the floor and projecting 25 cm from the north wall is a plaster-covered stone step 13 cm high.

PIT (Figs. 4.2b, Lot A-11; 4.8c). Beneath the plaster floor of the cist is a 7 cm layer of black earth. Lot A-11 is material from a pit 1.10 m deep and approximately the dimensions of the cist. The upper 60 cm of the pit are of open fill; the lower 50 cm, of earth and small stones.

4.2. Excavations in Group J-49, Plans and Sections.

a. Structure J-49a. Lot A-8. Contents of cist under south end of platform: broken chipped flint point, 4.7 cm long, Cat. no. 52-135; polished gray stone, 2.8 by 2.2 by 0.3 cm, Cat. no. 52-136; 6 fragments of obsidian chip blades, longest 3.8 cm, Cat. no. 52-137; sherds; Lot A-10: Contents of pit above floor (2) under north end of platform: 5 fragments of obsidian flake-blades, largest 4.3 cm long, Cat. no. 52-142 (Fig. 4.8c); 1 fragment of bone; sherds; Lot A-12: Contents of pit below floor (2) under north end of platform: flat pottery figurine or effigy head, greatest dimension 3 cm, Cat. no. 52-164 (Fig. 4.8c); obsidian flake-blade, 5.1 cm long, Cat. no. 52-144 (Fig. 4.8c); sherds; Lot A-22: Contents of pit under center of platform: objects not shown or described in Fig. 4.8e: 1 fragment of shell; sherds; 1. Debris line; 2. Plaster floor covering an area of 1 by 1.40 m. Tight fill of earth and stones below floor. b. Structure J-49b; Lot A-6: Contents of pit above cist under East Bench: fragment of obsidian flake-blade, 1.8 cm long, Cat. no. 52-143; bone fragment; sherds; Lot A-7: Contents of cist under east bench: fine-grained limestone mano, 14.4 cm long, Cat. no. 52-97; limestone rubbing stone, 7.2 cm across, Cat. no. 52-98; fragment of stone cylinder, 1.5 cm diam., 5.5 cm long, Cat. no. 52-99; fragment of shell; two flint chips; bone fragment; sherds; Lot A-9: Contents of pit under West Bench: shell bead, 1 cm diam; Cat. no. 52-133; flint tool (hatchet?), 5.5 cm long, Cat. no. 52-191; flint chip, greatest dimension 4.4 cm, Cat. no. 52-192; fragment of obsidian flake-blade, 2.6 cm long, Cat. no. 52-194; flint chip; shell fragment; sherds; Lot A-11: Contents of pit below cist under east bench A-7): 4 fragments of obsidian flake-blades, largest 2.8 cm long, Cat. no. 52-141; pieces of petrified shell; sherds; animal bones: ocellated turkey, iguana, cougar; 1. Bench; 2. Plastered stone step, floor turns up to it; 3. Plastered floor; 4. Passageway between benches.

4.3. Excavations in Structure J-50a, Plan and Section.

Lot A-13: Contents of midden under east bench and back room: objects not shown or described in Fig. 4.9: 7 miscellaneous seashells; 2 pieces of worked bone; 4 worked (?) pieces of deer antler, average 9 cm long, Cat. no. 52-110; 30 pieces of obsidian blades, Cat. no. 52-128; 12 pottery pellets; 3 branches of coral, Cat. no. 52-117; 45 flint chips; sherds; 2 fragments of human bone, animal bones: rabbit, dog, ocellated turkey, iguana, cougar, ocelot, cow's teeth, fish (tropical sea). The cow's teeth were presumably intrusive. Lot A-14: Contents of pit below center bench: fragment of worked stone, Cat. no. 52-150 (Fig. 4.8a); sherds. Lot A-15: Contents of tomb under west bench: limestone mano, 17.2 cm long, Cat. no. 52-157 (Fig. 4.8a); hammerstone, 6 cm diam., Cat. no. 52-165 (3) (Fig. 4.8a); fragment of obsidian flake-blade, 1.4 cm long, Cat. no. 52-147 (Fig. 4.8c); 37 large chips of gray flint; 2 fragments of shell; 2 flint chips; oval pebble; sherds; human maxilla; human long bone; 1. Upper edge of bedrock; 2. Capstone 25 cm thick; 3. Capstone 70 by 80 cm, found fallen.

WEST BENCH.

PIT (Fig. 4.2b, Lot A-9). Measures approximately 1 by 1.50 m by 1.50 m deep.

GROUP J-50

(305 N, 650 E)

STRUCTURE J-50A (Fig. 4.3), a well-preserved three-bench building with back room, is located

on the north edge of the terrace supporting two constructions.

EAST BENCH. A sunken area in the bench suggested the possibility of a tomb. Excavation revealed a natural pit filled with midden material.

PIT (Figs. 4.3, Lot A-13; 4.7c; 4.9, Lot A-13). The opening of the pit was partly closed by two large stone slabs. The pit from the lower side of the slabs to bedrock has a depth of 1.45 m. The east side is

4.4. Excavations in Groups J-50 and J-122, Plans and Sections.

a. Structure J-50b. Lot A-16: Contents of pit under south bench: crude flint point, 4.2 cm long, Cat. no. 52-154 (Fig. 4.8c); pieces of worked limestone, 4.3 cm long, Cat. no. 52-151; bone fragment; pieces of shell; sherds. Lot A-17: Contents of pit under north bench: crudely shaped limestone sphere, 6 cm diam., Cat. no. 52-153 (Fig. 4.8a); sherds. Lot A-21: Contents of pit in main platform supporting Group J-50, 5 m west of Structure J-50b; sherds. b. Structure J-122c. Lot A-5: Contents of cist under west end of platform: hammerstone, 6 cm diam., Cat. no. 52-693; pottery whistle, animal, greatest dimension 4.9 cm, Cat. no. 52-70; 11 fragments of obsidian flake-blades, Cat. no. 52-71; flint blade, 8.4 cm long, Cat. no. 52-723 carved shell ornament, 6.5 cm long, Cat. no. 52-73; perforated shell tinkler, 2.5 cm long, Cat. no. 52-74, also 3 odd pieces of shell under same Cat. no.; perforated animal tooth, 5.7 cm long, Cat. no. 52-75; 7 flint chips; sherds (one Plumbate); fragment of human bone; animal bones, ocellated turkey, raccoon (?), turtle, tapir tooth. 1. Entrance into cist.

defined by large rough masonry; the west side extends under a limestone ledge and yielded most of the material. The pit was followed under the natural ledge for a distance of 1.60 m.

MIDDLE BENCH.

PIT (Figs. 4.3, Lot A-14; 4.8a). A trench within the bench was extended to a depth of 70 cm, where bedrock was encountered. Sherds from this area are included in Lot A-14.

WEST BENCH.

TOMB (Figs. 4.3, Lot A-15; 4.8a; 4.9c). Measures 1 by 1.20 m and has a depth of 1.80 m from top of bench. The uneven floor is formed of bedrock. The west and south sides of the tomb are fairly well indicated by rough masonry. The stones used in the south wall are larger and more irregular than those of the west. The east wall is poorly defined. Portions of human upper jaw and a leg bone were found on the floor. On the floor near the northwest corner was a cache of 38 large flint chips and a mano.

STRUCTURE J-50B (Fig. 4.4a) is somewhat L-shaped so that there is a section of bench to the south and a section to the north. In good state

of repair.

SOUTH SECTION OF BENCH.

PIT (Figs. 4.4a, Lot A-16; 4.8c): Measures 1.20 by 1.80 m. Bedrock encountered 70 cm below top of bench.

NORTH SECTION OF BENCH.

PIT (Figs. 4.4a, Lot A-17; 4.8a): Measures 1.20 by 3.00 m. Bedrock encountered 40–80 cm below top of bench. Rock slopes downward from east to west.

TERRACE SUPPORTING GROUP.

PIT (Fig. 4.4a, Lot A-21): Roughly 1m square and located 5 m west of structure J-50a. Pit had a depth of 50 cm to bedrock.

STRUCTURE J-122C**(7 N, 645 E)**

STRUCTURE J-122C (Fig. 4.4b) is a bench 2.50 m, wide by approximately 5 m long defining the south side of a three-structure group. A semicircular depressed area in the west end of the bench and two jamb stones on the south edge of the terrace suggested a likely place to excavate.

CIST (Figs. 4.4b, Lot A-5; 4.6d). Semicircular, with an average diameter of 1.70 m. Crude masonry walls rise to within 12 cm of the floor of the terrace. Opening on the south 45 cm wide defined by two large jamb stones 75 cm high by 45 cm wide. Door sill and floor of the tomb of bedrock, very uneven and rough.

STRUCTURE 1-94**(15 N, 1075 E)**

This structure (Fig. 4.5) made up of three benches, is located on the south edge of a poorly defined terrace.

EAST BENCH. The east edge of the bench has collapsed and fallen down the slope of the terrace.

PIT (Fig. 4.5, Lot A-34). Measures 1 m wide by 2 m long by 1.80 m deep from top of bench to bedrock.

MIDDLE BENCH. Exposed capstone of a cist under the bench led to excavation.

CIST (Figs. 4.5, Lot A-27; 4.6c). Measures 70 by 90 cm. Walls 50 cm high formed of one and two courses of stones. Floor a 4 cm layer of plaster. No plaster on walls. Not vaulted. Two capstones rest on vertical walls. Underside of capstones 20 cm below top of bench. Entrance to cist through opening on south side where there are two large jamb stones. Trench to south of jambs showed no construction (Fig. 4.5, Lot A-29).

PIT (Fig. 4.5, Lot A-30). A pit beneath floor of cist, 80 cm deep to bedrock, showed fill of stones with small amount

**4.5. Excavations in Structure I-94, Plan and Section.**

No catalogue numbers have yet been given to objects recovered; sherd material has not yet been examined. Lot A-27: Contents of cist under center bench: shell fragment, obsidian fragment, sherds. Lot 8-28: Contents of top 60 cm in pit under west bench: worked flint 3.8 by 3 cm (Fig. 4.8f), sherds. Lot A-29: Contents of pit in terrace south of stone-lined cist in center bench (Lot A-27): piece of worked bone, piece of worked shell, piece of obsidian, sherds. Lot A-30: Contents of pit below floor of cist in center bench (Lot A-27): shell bead, flint chip, sherds. Lot A-31: Contents of pit below Lot A-28 in west bench: all objects but the sherds recovered are shown and listed in Fig. 4.8f; animal bones, ocellated turkey, turtle. Lot A-32: Contents of part of pit above floor (5) north of terrace supporting Structure 1-94: 5 pieces of obsidian, sherds. Lot A-33: Contents of pit below Lot A-32: 3 pieces of obsidian, sherds. Lot A-34: Contents of pit in east bench: 4 pieces of shell, 8 pieces of obsidian, sherds, fragment of human bone; animal bones, ocellated turkey, iguana. Lot A-35: Contents of pit between floors of terrace north of passageway between the center and west benches: piece of obsidian, sherds. Lot A-36: Contents of cist resting on floor (4) in pit north of passageway between center and west benches: sherds. Lot A-37: Contents of pit in lower terrace north of pit containing Lots A-32 and -35: sherds. Lot A-38: Contents of pit below Lot A-35: worked deer antler, 2 pieces of shell, 8 pieces of obsidian, sherds; 1. Capstones; 2. Entrance to cist; 3. Jamb of entrance; 4. Plaster floor; 5. Plaster floor.

4.6. Excavation in Structures J-131a, I-94, and J-122c.

a,b. Tomb under south bench of Structure J-131a, looking west. Cist under central bench of Structure I-94, looking north. d. Cist under west end of Structure J-122c, looking north.

of earth. Material recovered includes sherds, shell bead, and a flint chip.

WEST BENCH.

PIT (Figs. 4.5, Lots A-28,-31; 4.8f). Measures approximately 1.30 by 3 m high and had a depth of 60 cm from top of bench to work level on which facing stones of bench rested. Material from the area

(Lot A-28) includes sherds and a worked flint, ellipsoidal in shape, measuring 3 by 3.8 cm. Pit extended beneath work level to bedrock, a distance varying from 1.10 to 1.25 m (Lot A-31).

PITS ASSOCIATED WITH TERRACE OF STRUCTURE I-94. Various test pits were made in the terrace supporting the structure. For location of pits and description of the material recovered see Figure 4.5, Lots A-32, -33,

-35, -36, -37, -38. Sherds from Lot A-36 came from an irregularly shaped, stone-lined cist approximately 70 cm square and having a depth of 25 cm where

it rested on the plaster of an earlier terrace level. Lots A-33-37, and -38 are all from pits extended to bedrock.

4.8. Artifacts Recovered During Excavation in Groups J-49, J-50, J-131, and I-94.

a. Top: limestone mano, 17.2 cm long, Cat. no. 52-157, Lot A-15 (Fig. 4.3). Bottom, left to right, fragment of worked stone, Cat. no. 52-150, Lot A-14 (Fig. 4.3); hammerstone, 5.8 cm diam., Cat. no. 52-165 (3), Lot A-15 (Fig. 4.3); crudely shaped limestone sphere, 6 cm diam., Cat. no. 52-153, Lot A-17 (Fig. 4.4a). b. Lot A-2 (Fig. 4.1). Top, left to right, pottery figurine of a woman, 8.6 cm long, Cat. no. 52-64; pottery figurine of a man, 10.2 cm long, Cat. no. 52-65. Middle, deer antler, 9.9 cm long, Cat. no. 52-68. Bottom, left to right, shell ornament, 3.7 cm greatest breadth, Cat. no. 52-67; filed human tooth, Cat. no. 52-226; shell ornament perforated for suspension, 3.2 cm long, Cat. no. 52-66. c. Top, left to right, 5 obsidian flake-blades, largest blade 4.3 cm long, Cat. no. 52-142, Lot A-10 (Fig. 4.2a); 4 obsidian flake-blades, largest blade 2.8 cm long, Cat. no. 52-11 Lot A-11 (Fig. 4.2b); obsidian flake-blade, 5.1 cm long, Cat. no. 52-144, Lot A-12 (Fig. 4.2A); fragment of obsidian flake-blade, 1.4 cm long, Cat. no. 52-147, Lot A-15 (Fig. 4.3). Bottom, left to right, flat pottery figurine or effigy head, 3 cm greatest dimension, Cat. no. 52-164, Lot A-12 (Fig. 4.2a); chipped flint point, 7.4 cm long, Cat. no. 52-165 (1), Lot A-15 (Fig. 4.3); fragment of chipped flint point, 2.8 cm across, Cat. no. 52-165 (2), Lot A-15 (Fig. 4.3); crude flint point, 4.2 cm long, Cat. no. 52-154, Lot A-16 (Fig. 4.4a). d. Lot A-1 (Fig. 4.1). Top, left to right, flint blade 9.5 cm long, Cat. no. 52-62; shell ornament, 6.1 cm greatest diam., Cat. no. 52-61. Bottom, left to right, pottery whistle (seated monkey?), 4.2 cm long, Cat. no. 52-60; obsidian blade, 3.8 cm long, Cat. no. 52-63. e. Lot A-22 (Fig. 4.2a). Left: 4 obsidian flake-blades, longest blade 4 cm, Cat. no. 52-139; obsidian core, 9.3 cm long, Cat. no. 52-140. Upper right, worked limestone, 4.8 cm long, Cat. no. 52-152. Lower right, pottery spindle whorl, 3 cm diam., Cat. no. 52-149. f. All Lot A-31 except upper right which is Lot A-28 (Fig. 4.5). These artifacts have yet not been catalogued. Top, left to right, rubbing stone, one surface flat; fragment of rubbing stone; stone nose plug (?), 5.3 by 3.1 cm; fragment of green stone celt; worked flint. Lower left: 14 obsidian flake-blades. Lower right, flint arrow (?) point; 3 pieces of shell; perforated shell tinkler; worked bone; perforated animal tooth; fish bone.

4.9. Artifacts From Midden Under East Bench and Back Room of Structure J-50a, Lot A-13 (Fig. 4.3).

a. Top, left to right, 9 bone awls, awl at left is 12.8 cm long, Cat. nos. 52-106,-107; bone needle, 7.9 cm long, Cat. no. 52-108. Bottom: perforated animal tooth, 4.5 cm long, Cat. no. 52, one needle, point missing, 3 cm long, Cat. no. 52-127. b. 30 perforated human teeth, Cat. no. 52-121, appear to be 8 molars, 9 premolars, 3 canines, 8 incisors, 2 unidentified. c. Upper left corner: fragment of worked bone, 2.2 cm diam., Cat. no. 52-101. To right of Cat. no. 52-101: fragment of perforated mother-of-pearl shell, 3 cm long, Cat. no. 52-102. Below, Cat. nos. 52-101 and 52-102: 3 fragments of worked shell, Cat. nos. 52-103, -104, -105. To right of above: 10 perforated shells, 4 cm largest diam., Cat. no. 52-100; one unperforated shell. d. Upper left: pottery figurine head, 3 cm high, Cat. no. 52-120. Upper right, fragment of pottery whistle, 3.7 cm high, Cat. no. 52-123. Center: pottery spindle whorl, 3.2 cm diam., Cat. no. 52-118. Lower left: fragment of green stone celt, 2.9 cm long, Cat. no. 52-119. Lower right, pottery turtle or lizard head, 3.2 cm long, Cat. no. 52-122. e. Left: fragment of metate with leg, total height, 6.8 cm Cat. no. 52-111. Right: limestone rubbing stone, 10 cm long, Cat. no. 52-112. f. Top, left to right, broken chipped flint point or scraper, 4.1 cm long, Cat. no. 52-113; chipped flint point 7.5 cm long, Cat. no. 52-116. Bottom, left to right, chipped flint point or scraper, 5.3 cm long, Cat. no. 52-114; chipped flint point, 6.8 cm long, Cat. no. 52-115. g. Left to right, 2 large obsidian blades, largest 11.4 cm long, Cat. no. 52-125; obsidian point with very fine chipping on both sides of point, 3.7 cm long, Cat. no. 52-126.

CENOTE X-COTON AT MAYAPÁN

ROBERT E. SMITH

The cenotes of Yucatán have been studied by various people and institutions, notably H. C. Mercer (1896), L. J. Cole (1910), Carnegie Institution of Washington (see Pearse and others, 1936), Brainerd (1942), and Lothrop (1952). These studies have been primarily geological, hydrographic, and zoological, the archaeological aspect not being treated save by Mercer, Brainerd, and Lothrop. In this report I plan to emphasize the archaeological importance of one of the numerous cenotes at the ruins of Mayapán.

Cenote X-Coton is located in the southeastern section of Mayapán (Jones 1952, map, Square T) close to one of the seven main gates and a small group of ceremonial structures. It is one of 19 named cenotes found within the city wall and is of the type where much of the roof has fallen, but a considerable portion still remains (Figs. 5.1, 5.3; Cole 1910, Fig. 3; see also Pearse and others 1936:18, Fig. 3). The open southern part of the cenote is used to cultivate bananas. The local Indians get in and out by means

of tree roots which reach to the floor of the cenote. We used a 6 m ladder (Fig. 5.4b) for ourselves and employed ropes to lower equipment and remove pottery and other finds.
